The first chapter, Introduction

In order to improve the country car race smart students innovative and fun, inspire college students to participate in the competition Hing

Fun, improve the abilities of students, innovation and the ability to accept the challenge, smart car race committee will group than electromagnetic

Cars predetermined game is upright, as shown in 1-1 Fig. Cars of walking two other groups remain unchanged.
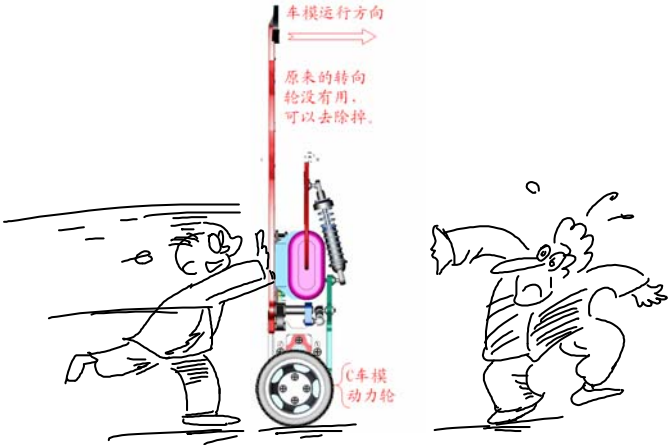

Map 1-1 Electromagnetic operation mode set upright Cars

Cars walk upright game is modeled on two traveling mode requires self-Ping Heng electric vehicle, so car models with two rear wheels

Driving of walk upright. In recent years, two self-Ping Heng electric vehicle running its flexible, convenient, energy-saving features to give

A lot of development. There are many domestic and international research in this area, but also the appropriate product. In the electromagnetic's race, using

The original C Type dual rear-wheel drive car models characteristics, to achieve self-Ping Heng two walking. Compared with the traditional four-wheeled vehicle trave

Modeling contest mode, scale models to walk upright in hardware design, control software development and on-site commissioning and put forward higher

Requirements. In order to be able to help participating students made car models as soon as possible participate in the competition, the competition secretariat has p

Li reference design walking. Team members can be on this basis, further improve the hardware and software solutions to improve

The level of competition.

To accommodate beginners, the program describes the process, the derivation formula to minimize the use of scientific language popular media

Shao control theory and method, given C The core part of the process of making the type of car models. The main content of the paper is organized as shown 1-2

To help students perform debugging car models, Appendix 4 Cars are given guidelines - and the related video site.

Cars can get an intuitive feel as soon as possible by adjusting the parameters of such information.

Chapter II, Part principle

2.1 Upright task decomposition

Cars match the requirements set electromagnetic performed in an upright state along a track to match two wheels, as compared to four

The ground state, the task is more complex control car models. In order to facilitate the solution to the problem can be found, first of all complex

Problem into simple questions for discussion.

The rules of the game required to maintain car models may be able to design many upright of the program, the program is assumed that the reference dimens

Cars held upright, the power running car models are derived from the two wheels. The rear wheel is driven by two DC motors.

Therefore, from a control standpoint, as a control target car models, which is a control input of the rotational speeds of the two electrodes.

Cars motion control tasks may be decomposed into the following three basic control tasks as twenty one Below:

(1) Ping Heng control Cars: Cars upright holding reverse motion to the Ping Heng state by controlling two motors;

（2）Speed control car models: Cars speed control is achieved by adjusting the angle of the car models, in fact, finally

To control the evolution of the wheel speed is achieved by controlling the motor speed.

（3）Direction control Cars: Cars steering control is achieved by controlling the rotational speed differential between the two motors.
Map twenty one Cars control task decomposition

Cars vertical direction and two control tasks are directly controlled by the rear-wheel drive motor car models completed. Assume car

Mode virtual machine can be broken down into two different functions of the drive motor, which are connected coaxially, respectively, to control the linear Cars

Li Ping Heng, the left and right direction. In actual control, the control signal is superimposed and controls vertical direction with car models plus

Upload motor, as long as the motor in the linear state to complete the above two tasks simultaneously.

Cars speed by adjusting the inclination to complete car models. Different car models inclination causes acceleration and deceleration of the car models,

So as to control the speed of.

Map twenty two Cars inclination will cause changes in vehicle speed

After the task decomposition three independently controlled. As the final are on the same electrical control object (car models

Machine) is controlled, there is a coupling between them. For analytical purposes, it is assumed in the analysis of one of the other

Control objects have stabilized. For example, in the speed control, it is necessary to control car models have been able to stay upright; square

When the control requires speed car models and can maintain a constant Ping Heng; Similarly, when the Ping Heng control car models, need

Speed and direction control has reached a plateau. These three tasks remain Cars balance is the key. Since the car models as well as by

Effect of the three control, from the point of view of Ping Heng control car models, it becomes the other two control interference. therefore

Controlling the speed of the car models, the direction should be kept smooth to reduce interference to the balance control. Speed adjustment

For example, the need to change the set value of the inclination Cars Cars Ping Heng control, thereby changing the inclination angle of the actual car models. for

The Ping Heng control to avoid the impact of car models, car models change this inclination need be very slow. This will be after

Face velocity control is discussed in detail.

FIG mating between the three twenty three Fig.
Map twenty three Mutual cooperation between the three control

The following three implementations are discussed control task decomposition car models.

2.2 Cars Ping Heng control

Cars Ping Heng of control and intuitive experience from daily life experience. The average person through simple exercises you can

Let a straight stick upright on the fingertips. This requires two conditions: one is the palm holding the stick may be moved;

Another can observe the eye inclination angle and the inclination tendency of the stick (angular velocity). Offset by moving palm tree

And the inclination angle of the rod tendency to stick in the upright. These two conditions are indispensable, in fact, in control

The negative feedback mechanism, see Fig. twenty four .

No genius a blindfolded acrobat can make stick upright on his fingertips in the world, because

For the eyes observed no negative feedback.
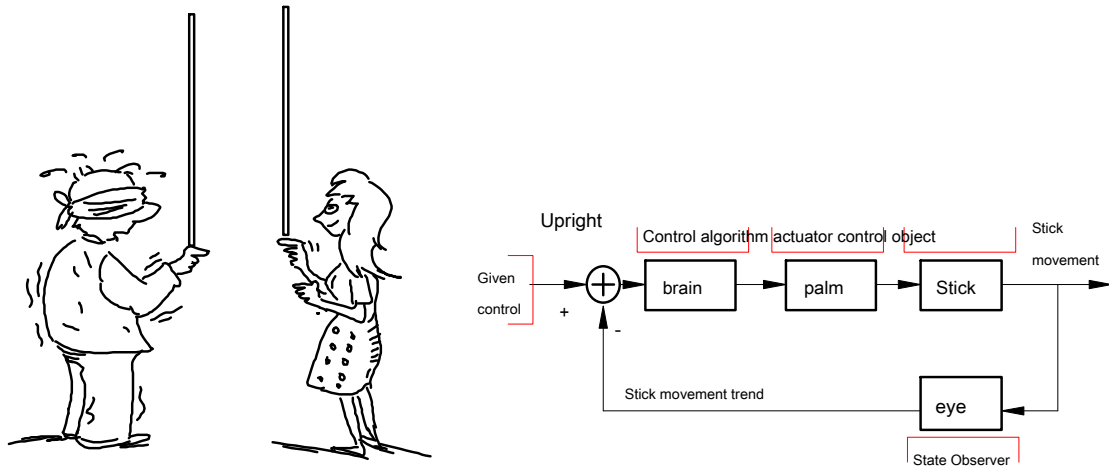

Map twenty four Feedback control to maintain an upright stick

Cars Ping Heng control is achieved through negative feedback, maintains the upright stick above comparison is relatively simple. because

Cars for the two wheels touch the ground, the body will only tilted on wheels rolling direction. Controlling rotation of the wheel, offset

In one dimension sloping trend can keep the body balanced. Figure 2-5 Fig.

■ The vehicle body vertical wheel remains stationary.

★ Vehicle body tilt to the left, the left wheel acceleration operation.

○ The vehicle body is inclined to the right, the right wheel acceleration operation.
Map 2-5 Cars by motion of the wheel to maintain Ping Heng

So how the wheels run, finally be able to maintain the body Ping Heng and stability? To answer this question, you can

Cars establish mathematical models of kinematics and dynamics, design feedback control to ensure Ping Heng of the car models. In order to make the students

We were able to more clearly understand the physical processes of them. Cars now be described to maintain balance control by comparing the pendulum model

System of law.

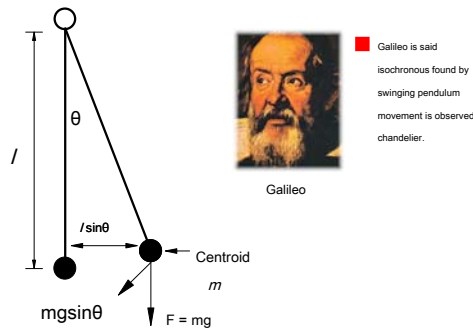

Map 2-7 Ordinary pendulum Stress Analysis

When the object away from the vertical equilibrium position will be subject to the action of gravity and force of the suspension wires, driving reply weight

Ping Heng position. This force is referred to as a restoring force, the size of

$$F = mg \quad \sin \theta \approx - mg \theta$$

In the offset angle is small, and the return force is proportional to the angular deviation between the magnitude in the opposite direction. here

Restoring force, the pendulum will conduct periodic motion. Pendulum motion in the air, due to the damping force of the air,

Pendulum eventually stops in a vertical Ping Heng position. Pendulum damping force proportional to the velocity of the air, in the opposite direction. Block

Larger damping force, the pendulum will be stabilized in the vertical position as soon as possible. Map 2-8 Exhibit different damping, pendulum

Motion profile.
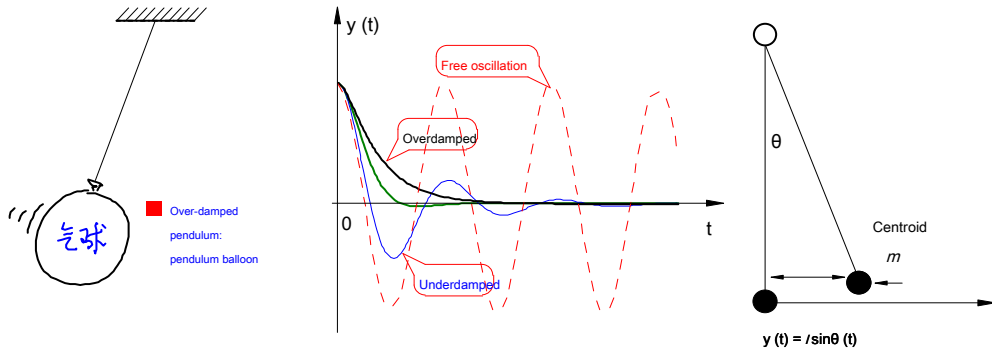

Map 2-8 Pendulum motion under different damping force

Summary pendulum can be stabilized in the vertical position of the two conditions:

(1) By the displacement (angle) opposite to the restoring force;

(2) Opposite to the damping force by velocity (angular velocity).

If no damping forces, the pendulum swings around a vertical position. Pendulum damping force will make the final stop in

Vertical position. The damping force is too small (less damping) makes the pendulum oscillates back and forth in the attachment position of Ping Heng. The d

Large (overdamped) will be such that the Ping Heng position of the pendulum reaches longer time. Thus there is a critical damping coefficient, the

At the time was the shortest pendulum stable equilibrium position.

Why pendulum in a vertical position, when subjected to external disturbances, we can not maintain stability? Minute

Analysis of the inverted pendulum force, as 2-9 Fig.

Map 2-9 Cars in the frame of reference on the wheel Mechanical Analysis

The reason is not inverted pendulum like a pendulum in the vertical position as can be stabilized, because of its deviation from Ping Heng position

When restoring force and displacement suffered the same direction, rather than vice versa! Thus, the inverted pendulum will deviate from the vertical acceleration

14

Position until the fall.

How can control such as an inverted pendulum pendulum as stable in the vertical position it? To achieve this goal,

Only two ways: one is to change the direction of gravity; the other is the additional force, so that restoring force and displacement

In the opposite direction the job. The second method is clearly only be able to do.

The bottom of the inverted pendulum control wheels, so that it An accelerated. Such carts standing (non-inertial reference frame, the wheel for

The origin of coordinates) Analysis pendulum force, it would be an additional inertial force, the force and direction of the wheel acceleration phase

Instead, proportional to the size. Such inverted pendulum restoring force suffered as:

$$F = mg \sin\theta - ma\cos\theta \approx mg\theta - mk_1\theta \qquad (2\text{-}1)$$

Where, due to the θ Small, so it was linearized. Negative feedback control is assumed that the wheel acceleration and angle θ Positively

Ratio, ratio. If the ratio $k_1 > g$, (the acceleration of gravity) so restoring force to facilitate the displacement direction relative to a direction

Inverted.

Further, in order that the inverted pendulum can be stabilized as quickly as possible in a vertical position, but also necessary to increase the damping force. a

There is an air damping force and frictional force, the damping force is relatively small. Therefore it requires an additional control damping force. increase

Adding a damping force proportional to the speed and the angle, in the opposite direction. Therefore formula (2-1) May become

$$F = mg - mk_1\theta - mk_2\theta' \qquad (2\text{-}2)$$

According to the above control method, the inverted pendulum model becomes pendulum model can be stabilized in a vertical position. therefore,

Control algorithm may have control of the wheel acceleration

$$a = k_1\theta + k_2\theta' \qquad (2\text{-}3)$$

In the formula, θ Cars of inclination; θ' Angular velocity; k_1, k_2 Are scale factor; after adding two wheel acceleration as

The amount of control. Just make sure $k_1 > g$, $k_2 > 0$ Under conditions, such as car models as the pendulum is maintained in an upright state.

Wherein there are two control parameters k_1, k_2, determine whether the car model can be stabilized to a vertical Ping Heng position, it must be greater than the weight

Acceleration force; k_2 determines the vertical position back to the car model damping, the damping coefficient may be selected to ensure proper Cars

Stable in the vertical position as soon as possible. The role of these two coefficients **Map 2-10 Fig.**
Map 2-10 Cars two control coefficients action

In the above simple analysis, obtained by analogy with the inverted pendulum control scheme upstanding car models. Below the inverted car models

Simple mathematical modeling, the ratio of the speed differential and the establishment of negative feedback control, control theory to discuss the basic car models

Maintaining stable conditions by closed loop control.

Simplifying assumptions inverted car models with a height of L , The quality of m The simple pendulum, it can be placed around the moving

The wheel. Suppose disturbance caused by the angular acceleration produced. Model cars to be forced direction perpendicular site

Analysis can be obtained with the inclination motion of the wheel acceleration car models and acceleration disturbance Movement between the parties

Cheng. Figure 2-11 Fig.
车模运动方程

$$L\frac{d^2\theta(t)}{dt^2} = g\sin[\theta(t)] - a(t)\cos[\theta(t)] + Lx(t)$$

在角度 θ 很小时，运动方程简化为：

$$L\frac{d^2\theta(t)}{dt^2} = g\theta(t) - a(t) + Lx(t)$$

车模静止时：$a(t) = 0$

$$L\frac{d^2\theta(t)}{dt^2} = g\theta(t) + Lx(t)$$

Map 2-11 Cars equations of motion

When the corresponding stationary car models, the transfer function of the system inputs and outputs:

$$H(s) = \frac{\Theta(s)}{X(s)} = \frac{1}{s^2 - \dfrac{g}{L}}$$ In this case the system has two poles $_p = \pm\sqrt{\dfrac{gs}{L}}$ A pole at s flat

Right half-plane, car models and therefore unstable. Cars proportionality, after the differential feedback system as shown below:

$$X(s) \rightarrow \boxed{L} \rightarrow \xrightarrow{+} \bigoplus_{-} \rightarrow \boxed{\dfrac{1}{Ls^2 - g}} \rightarrow \Theta(s)$$

$$\boxed{k_1 + k_2 s}$$
Map 2-12 System block diagram of the proportional and differential feedback is added

The system transfer function is: $H(s) = \dfrac{\Theta(s)}{X(s)} = \dfrac{1}{s^2 + \dfrac{k_2}{L}s + \dfrac{k_1 - g}{L}}$. At this time, two system poles in:

$$s_p = \dfrac{-k_{two} \pm \sqrt{k_2^{twenty} - 4L(kg_1 -)}}{L}$$. The system requires two stable poles are located s The left half plane. To meet

This requires $kg k$, $_2 > 0$. It can be concluded, when $kg k$, $_2 > 0$ When upright car models can be stabilized.

This and the previous analysis is consistent with the conclusions reached by.

Feedback control the angle, and the angle is proportional to the control amount called proportional control; control proportional to the angular velocity

Differential control system referred to the amount (the angular velocity is a differential angle). The $k_1 k_2$ above therefore proportional and derivative coefficients are referre

System parameters. Wherein the differential parameter corresponds to the damping force, the shock can be effectively suppressed car models. By differential inhibiti

The idea is also applicable in the latter the speed and direction control.

Cars are summarized upright stable control conditions were as follows:

(1) To accurately measure the inclination Cars θ The size and the angular velocity size of;

(2) May control the acceleration of the wheel.

The first condition, that is, how to measure tilt angle and the speed of the car models. See the next section "Cars angle measurement."

How to determine the control parameter adjustment parameters see "Debugging chapter" in the. The following first discuss the implementation of the second conditi

I.e., acceleration of the wheel control.

Cars speed and acceleration is achieved by controlling the speed of the wheel, two rear wheels by the motor car models by

Driven by a reduction gear box, motion control can be achieved by controlling the motor speed of the wheel.

Movement of the motor control serves three purposes:

(1) Achieved by a motor acceleration control Cars stable Ping Heng. Wherein the control law is given by one;

(2) By the motor speed control, constant speed running and stationary car models. Although there are no rules to this game

Cars seeking constant speed, there is no requirement to maintain a stationary state after Cars crossed the line and before the game. By speed

Control, stability can be improved car models. In the future the game, if the rule increases the static requirements, or need to pass

When over-bridges and other obstacles, speed control will play a role.

(3) By a motor differential speed control, direction control can be realized car models. Differential control method see below "car

Direction control mode. "

Motor motion control by changing the magnitude of the voltage applied to the driving achieved. For electromagnetic mode of the motor

Type, and the dynamics model kinetic model of car models and simplify the analysis, the motor speed may be applied thereon

The relationship between the voltage reduced to the following first-order inertia model. Applying a step voltage to the motor, $Eu(t)$

number. Corresponding to different voltages, the motor speed curve in FIG. 2-13 Fig.
Map 2-13 Motor speed variation at different line voltages

From Fig. 2-13 As can be seen, the motor is significant in two stages: The first stage is the acceleration stage; a second

Stage for the constant speed phase. Wherein the acceleration stage, driven by the motor car models rear wheel acceleration, acceleration approximation

And is proportional to the voltage applied to the motor, the length of time depends on the time constant of the acceleration T_1 phase. This constant by a motor

Moment of inertia, the reduction ratio of the reduction gear box, the moment of inertia of the car models, typically in more than ten to hundreds of milliseconds. In con

Speed stage, motor driven rear wheel Cars constant speed, the speed is proportional to the voltage applied to the motor.

Cars angle adjustment control cycle is very short, typically a few milliseconds of time, much less than the time constant T_1 At this time, electric

Machine runs substantially during the acceleration phase. by(2-3) Acceleration control amount calculation obtained is multiplied by a scale factor,

Is the control voltage applied to the motor, so that it can control the car models is upright.

Acceleration of the motor is actually determined by the electromagnetic torque produced by the motor current. Taking into account the motor current

The control requires a higher speed, so in this motor control scheme can be simplified.

2.3 Cars angle and angular velocity measurements

Introduced in a control algorithm for controlling the upright car models, the car controlled by measuring the inclination angle and the speed of the car models

Wheel acceleration mode to eliminate the inclination of the car models. Thus, scale models and measuring the inclination angle becomes a speed control car models

The key upright. Cars and inclination angle measurement speed can be mounted on car models by an acceleration sensor and a gyro

achieve.

(1)Accelerometer

The acceleration sensor may measure gravitational acceleration due to the Earth movement of the object or produced. Contest rules governing

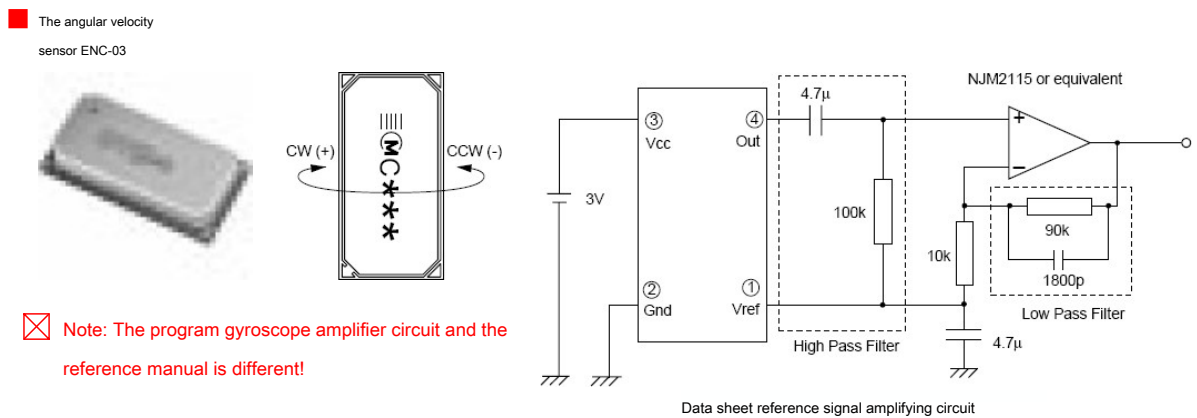

Map 2-19 The angular velocity sensor and reference amplifier circuit

A gyroscope mounted on a car model, car model may be measured inclination angular velocity, the angular velocity signal can be integrated to give

The inclination of the car models. Figure 2-20 Fig.
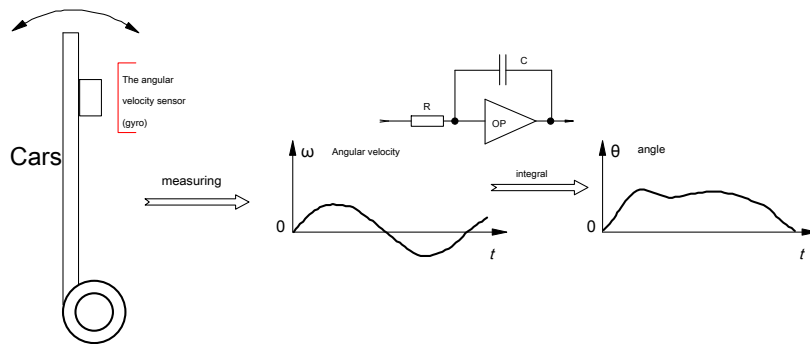

Map 2-20 Angle obtained by integrating the angular velocity

Since the output of the gyroscope is the angular velocity of car models, is not affected by body movement, so that the noise in the signal

Small. Cars angle is obtained by integrating the angular velocity, which may further smooth the signal, so that the angle of the letter

No more stable. Cars therefore necessary for the control angle and the angular velocity of the gyroscope signal can obtained.

Since the angle information obtained from the angular velocity gyro, need to go through integral operation. If there is a slight angular velocity signal

The bias and drift, after integration operation, change their cumulative error. This error will gradually with time

Increases, eventually leading to the saturation circuit, the signal can not form right angles, as shown in 2-20 Fig.
Map 2-21 Angular velocity integration drift

How to eliminate the accumulated error of it?

A simple method is obtained by the above angle information of the acceleration sensor to correct this. by

Comparative integrating the angular acceleration of gravity resulting angle obtained using the deviation therebetween changes gyroscope

Output, so that the integration phase angle tracking the angle of the acceleration sensor is obtained. Figure 2-22 Fig.
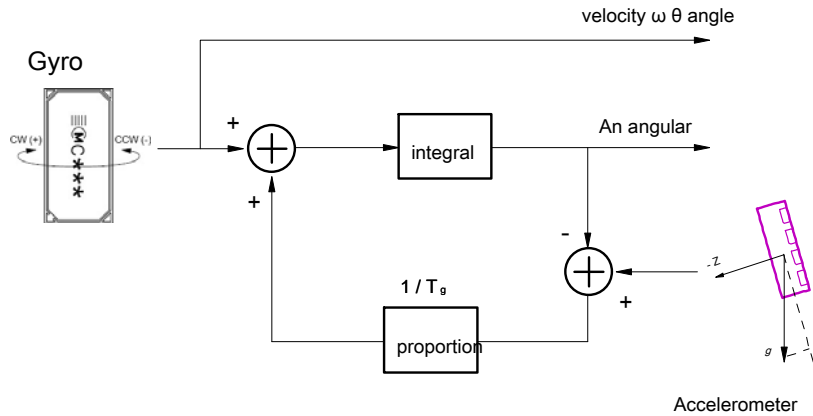

Map 2-22 The gyroscope to correct the drift angle by gravitational acceleration

Representing, through the comparison of the proportional After amplification and then into the angular velocity signal is superimposed after the output of the gyroscop

Line points. For a given angular accelerometer $_g$ θ, After proportional, integral part of the generated angle θ Would ultimately

equal $_g$ θ.

Write map 2-22 System transfer function can be seen that the output angle contains two first-order inertia. among them

The first is the acceleration due to gravity Z Axis corresponds to the angle, the second gyroscope inertia value after acceleration. system

Pure integrator system no longer exists, so that small deviations do not form rate gyro error accumulation. Where the parameter

T_g Determines the time constant of these two aspects of inertia. $_g$ T The larger, the tracking angle output Z The slower the output shaft, but can have

Noise suppressing effect on gravity accelerometer. $_g$ T Is too large, the gyro output error will be enlarged. The parameters need to

Cars actual operating results adjusted, the latter method described in "Cars debugging chapter" in the.

In order to avoid the output angle θ Tracking time is too long, you can take measures following two aspects:

(1) Careful adjustment of the amplifier circuit of the gyroscope, the bias so that it is as close to zero set value, and stable

set.

(2) And the start of the control circuit running, keep car models in an upright state, so the outset

Such that the output angle θ versus. Thereafter, the output of the accelerometer only cancel the offset of the integrator, the output angle will not

Great deviation.

An accelerometer to correct the gyro drift is only a method in which integration. Car model can also be measured by

Speed and acceleration of the gyroscope to correct the drift of the integrator, so that the acceleration device can be omitted. This control party

Method of speed control are given later.

(3) Double angle of the acceleration sensor and the angular velocity obtained

In Fig. 2-18 The acceleration sensor shown Z Addition to the output axis signal caused due to the acceleration of gravity, further

Car model information including angular movement and an acceleration generated. In the conventional car models on the basis of the parameters, the signals

There is not much difference in terms of amplitude, frequency, etc., are added together can not separate them. If on the other car models

Add the outer one acceleration sensor, the acceleration sensor mounting two different heights, then through two

The difference signal is determined angular acceleration of the car models. Figure 2-23 Fig.
Map 2-23 Double angular acceleration sensor obtained Cars

Two vertical acceleration sensors by subtracting the output signals, it can be obtained Cars angle acceleration. For this

Signal integrated twice, you can get the angular velocity and the angle of inclination of the car models. For product integration may bring

Points drift can still eliminate gravity accelerometer compensation method above.

The first two sections introduces Cars angle control and angle measurements, can be obtained Cars angle control block scheme

Fig.
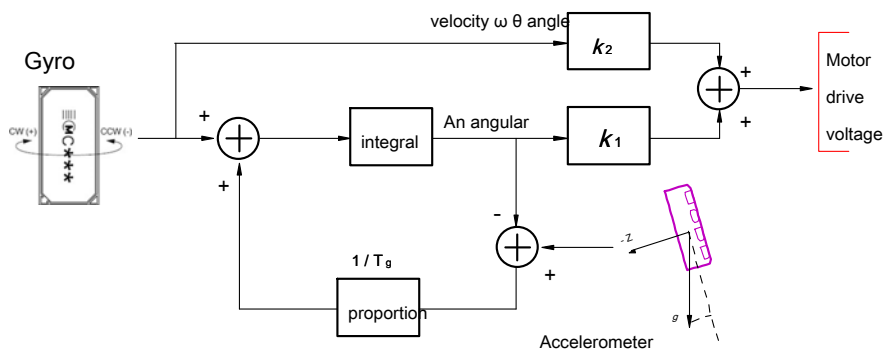

Map 2-24 The angle control block

The program used by the gravitational acceleration and gyroscope fusion complementary way to obtain an angle and the inclination angular velocity Cars

Degree, by the two proportional constant weight, to control the motor drive voltage such that the respective car models generated acceleration is maintained

Upright car models.

In this scenario, it is necessary to ensure that the accelerometer is mounted Z Cars vertical axis strictly perpendicular axis. Such as

If the angle deviation occurs, the actual result of the control is not strictly perpendicular to the ground car models, but there is a corresponding

inclination. Under the action of gravity, scale models will accelerate progress toward one aspect. In order to maintain a constant speed or stationary car models

This movement needs to eliminate installation errors. The actual car models in the production process requires mechanical adjustment and parameter setting softwar

Home. Further stability required to achieve speed control by the speed of the software.

Cars in Cars angle deviation angle control such that the acceleration generated in the direction of car models inclined. This one

The results can be used to control the speed of the car models. The next section will use this principle to regulate the speed of the car models.

2.3 Cars speed control

For controlling the speed with upstanding car models for controlling the speed of an ordinary car model is more complex. Because of the speed control

It is necessary to always maintain Ping Heng during car models, and therefore can not directly control the speed of car models by changing the motor speed Lysaght

Now. The following car models to analyze the reasons what caused the speed of change.

Cars in the above assumed vertical adjustment has been able to control the balance, but due to mounting error sensor

The actual measured angular deviation angle car models, and therefore is not actually holding Cars perpendicular to the ground, but there is a

inclination. Under the influence of gravity, will accelerate progress towards Cars inclined. Map twenty two It shows this relationship. control

As long as the system speed by controlling the angle of the car models can be achieved. Concrete realization of the need to address three questions:

(1) How to measure the speed of car models?

(2) How to achieve vertical control by changing the angle of the car models car models?

(3) How to control the angle of the car models based on the speed error?

The first problem can be measured by the wheel speed car models installed in the optical code wheel motor output shaft. Such as

Map 2-25 Fig.
Map 2-25 Motor speed detection

The control counter measures the number of microcontroller fixed time interval velocity electrical pulse signal may reflect

Machine speed.

The second problem can be solved by controlling the angle of a given value. Cars upstanding given setpoint control, the angle

Under the control of regulating, car models automatically maintained at an angle. Standing in front of car models control algorithm may know, the car

The final track is the acceleration of gravity tilt module Z The angle of the shaft. Therefore, the inclination car models given value and the acceleration of gravity Z Axi

Subtraction, we can finally decided inclination car models. Figure 2-26 Fig.

stability. However, based on actual experience, speed control car models can tilt control. In order to get a reasonable

Conclusion The experience of control, we need to speed in front of negative feedback control problem simplify the modeling analysis. Simplifying assumptions made

as follows:

(1) Cars angle reduced to a first order transition under control of the upright 1 $\dfrac{}{T_z s + 1}$. See the previous section of this

Finally, the conclusion of two problems.

(2) Cars tilt motion is generated by the wheels, so the wheel speed is multiplied by the derivative variable inclination Cars length.

(3) Ignore Cars dip caused by the wheel acceleration. Since the beginning of this discussion only control short transition phase

For segment, this time due to the relatively small car models angle, causing the rate of change is small.

(4) Systems, the speed ratio of the negative feedback.

Simplified model of FIG. 2-28 Fig.
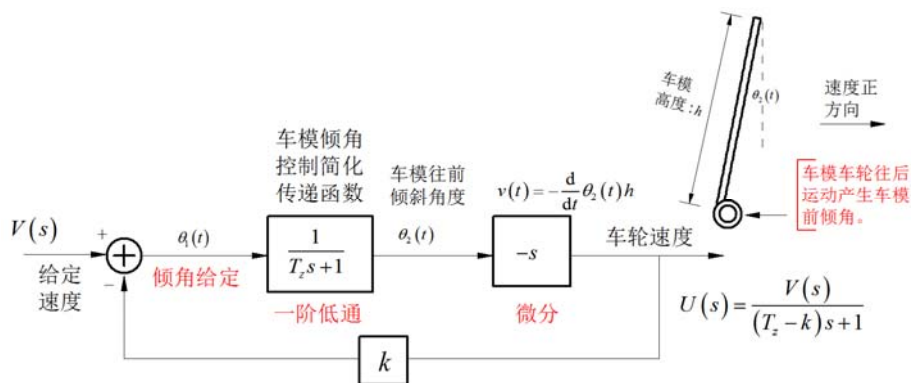

Map 2-28 Cars tilt control analysis

28

Transfer function analysis system simplification, having a first-order pole 1 $\dfrac{- - .}{T_z\,k}$ To ensure system stability, need

To meet. This requires adjustment of tilt Cars larger the time constant T_z, slow and smooth speed adjustment, while

Feedback proportional speed k is smaller. This conclusion is consistent with the actual experience.

The above two points may be smoothed by filter changes the control period, the control parameter is reduced, the method implemented in the program signal

Wave etc. to achieve. Specific can be found in Part V software code.

After achieving the above two points, and then analyze the stability of the moving speed car models. To simplify the analysis, first of all ignored

Cars speed due to changes caused by the tilt control. Cars speed final acceleration generated by the inclination of the decision, because

This will dip by integrating the speed of movement will be able to get car models. At this time, the speed control block diagram in FIG Cars 2-29 The

Shows.
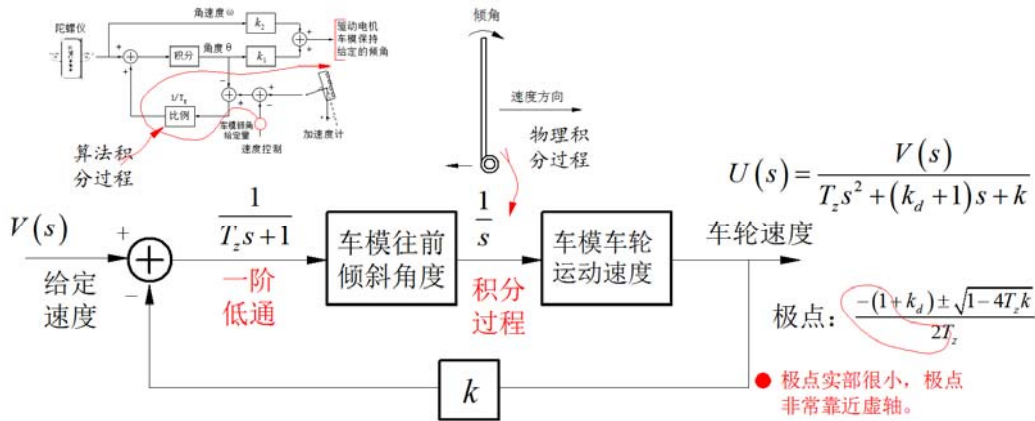

Map 2-29 Cars simplified model velocity control

To ensure the above analysis found that the system is stable, the inclination car models often take a large time T_z constant control. This will

It will cause the system to produce two conjugate poles, and real pole becomes small, so that the speed control system will generate

Shock phenomenon. This phenomenon can be observed in real time parameter tuning. So how to eliminate the speed control process

The shock of it?

To solve the problem of control shock, has been the experience in front of the car models angle control, that is in the control feedback

Increase the speed differential control. Figure 2-30 Shown
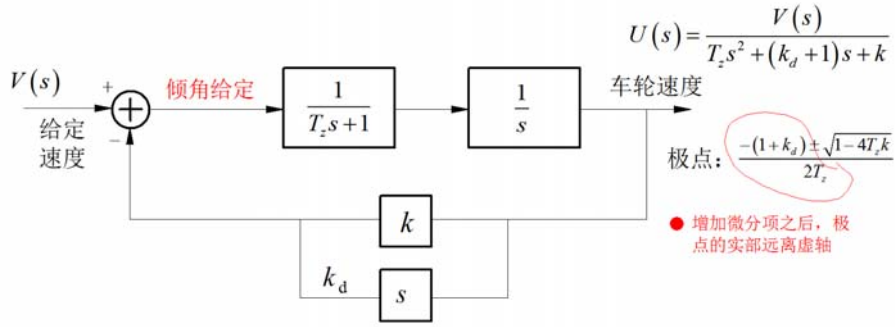

Map 2-30 Increase the system after the differential control

At this time the real pole of the transfer function of the system becomes large, convergence speed of the system.

Since the wheel speed feedback signal often there is noise, the speed differential operation will further increase the noise

Impact sound. This requires improvements to the above control method. The original system time constant inclination adjustment process is often very

Large, the system can be approximated by an integrator. The original part of the differential and integral part of this merger,

Forming a proportional control link. This keeps the system control transfer function unchanged, while avoiding differential calculation.

Specific improvements in FIG. 2-31 Fig.
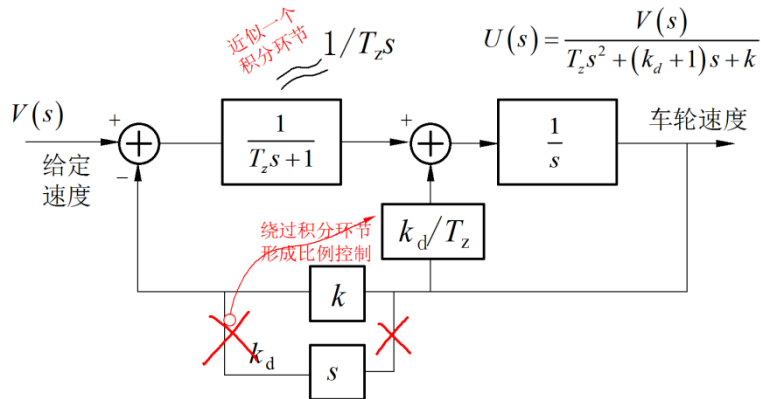

Map 2-31 Improved differential control

These improvements can be avoided for the differential velocity feedback signal, the feedback control, the feedback signals but using

The proportional and derivative, integral error no interest, so in the end the speed control is controlled residuals. But a direct quote

The error integral control link, will increase the complexity of the system, for the integral control is no longer increased, but by the angle

Performing the improved control of the combination.

Connection with FIG. 2-26 Cars angle control angle given gives a block diagram of the FIG. 2-31 After introduction of an angle formed Cars

And speed control block diagram. Figure 2-32 Below:
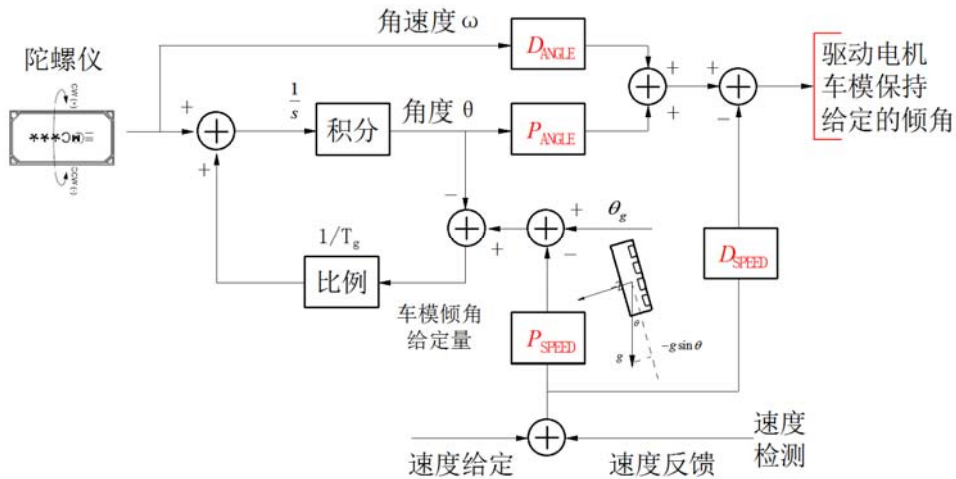

Map 2-32 Cars angle and speed control block

In the figure, the angle control requires two control parameters, the control parameters are the proportional P_{ANGLE} and differential control parameter

number D_{ANGLE}. Speed control also has two parameters, the control parameters are the proportional and differential P_{SPEED} control parameter

D_{SPEED}. In both of the differential control they are used to control the aim of increasing the angle and speed of the car models stability,

Control to prevent overshoot. This experience still applies in the direction of control in the back of the car models.

Below for FIG. 2-30 Control program for a further two points into improved. First, FIG. 2-32 Control scheme is given for

Integrating the speed error is not controlled, so that the final velocity is not strictly equal to the set value. Cars such as the requirement in the original

Stop, speed 0 . However, due to the use of proportional control, if at this time the gyro drift, or acceleration

Sensor mounting error, the final car models without the final adjustment to the inclination 0 , Scale models will run inclined towards constant speed

Down. Note that this time will not be like no speed control car models that run faster, but speed is not final 0 . for

This error elimination can be integrated directly Cars tilt compensation amount is set at an angle in the control output, which would Toru

Bottom elimination rate control error. Second, due to the addition of the speed control, which compensates for the gravitational acceleration and gyroscope

Drift and errors. Therefore, the accelerometer at this time is not actually necessary. The sensor may thus go

Out, but still retains the proportion of negative feedback loop, which is used to overcome the integration gyro drift. Comprehensive improvement on two points,

Map 2-32 It may be modified as shown in FIG.

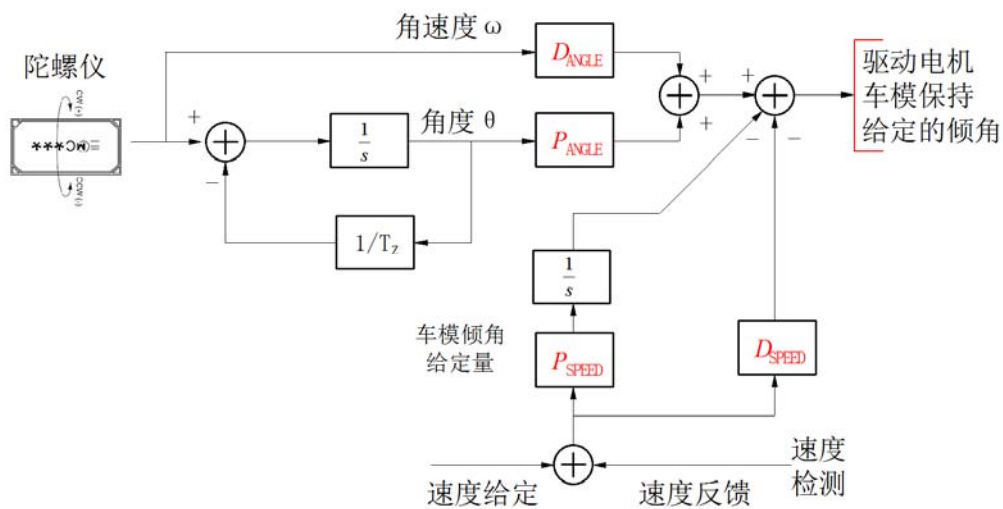

Map 2-34 Improved speed and angle control scheme

Map 2-34 No gravitational acceleration sensor, a speed control loop can compensate for the error sensors. At this point Cars

When the control starts, it is necessary to maintain a vertical position of car models. At this time, the angle of the gyro integrator is also initialized 0 .

Of course, if the circuit has been included in the accelerometer, this part may be retained, thereby improving the stability of the car models

Qualitative. In the latter given final control scheme, the control circuit retains this section.

In Fig. 2-34 Through speed control error directly proportional integral and superimposed on the motor control amount. Speed control

When discussing the start is achieved by adjusting the inclination car models, simplified and improved by the above performed, and finally in FIG.

2-34 It has been turned into a direct control of the motor. Please note two points: the first point is the amount of pole speed control

A negative resistance, and the polarity of the normal speed feedback control. " On the contrary "This is because the control scheme is adjusted from Cars

Design angle feedback and modifications obtained. The second point is that two control parameters correspond to the product of the error signal

Points and the proportion of value, so in some cases may be referred to these two parameters is integral and proportional control parameters.

2.4 Cars directional control

Cars achieve directional control is the key to the car models along a road race competition. Cars upright electromagnetic group resides

There is a paved road centerline enameled wire, inside pass there 100mA of 20kHz Alternating current. Therefore, in the center of the road

A generating line around an alternating magnetic field. By road centerline deviation detecting electromagnetic motor and differential control to achieve directional con

System, thus further ensuring Cars on the track. In the following we will be introduced separately.

(1) Deviation detecting electromagnetic road centerline

Electromagnetic road centerline detection method can be a simple two by electromagnetic induction coil mounted in front of the real car models

Now. Coils commonly used 10mH The H inductance. Figure 2-35 Fig.
Map 2-35 Wire detection center of the road way

Detailed reference design please see documentation "electromagnetic group race car model reference designs, 2010 . " behind

It gives the specific circuit design of circuit design.

(2) Motor differential control

(3) Direction control algorithm

Direction of the control algorithm to generate the electromagnetic induction voltage differential control of the motor car models in accordance with the detectio

Cars driving speed difference steering to eliminate the deviation from the center of the road car models. By adjusting the direction of car models, coupled with the veh

Line movement, you can gradually eliminate the difference in distance from the center line of the car models. This process is a process of integration, so car

Differential control mode typically requires only a simple proportional control can be done to control the direction of car models. However, because this car models

Body mounted relatively heavy object such as a battery, has a large moment of inertia appears during adjustment car models oversteer

Overshoot, if unchecked, will make the car models off the track. The foregoing angle and speed control experience for

The elimination of car models in the direction of control overshoot, need to increase the differential control.

Derivative control is based on a rate of change of the direction of car models differential control amount for correcting the motor control, so

Necessary to increase the rotational speed detection sensor car models. It can be detected using a gyro sensor, FIG. 2-37 The

Shown in FIG. 2-37 Cars gyroscope detecting rotational speed. Cars are also used in the gyro tilt detection.

2.6 Cars upright overall control algorithm of FIG.

By the above description, the car models upright main control algorithm together, in conjunction with FIG. 2-34 And 2-39

Forming a control block diagram of the overall algorithm as 2-40 Fig.
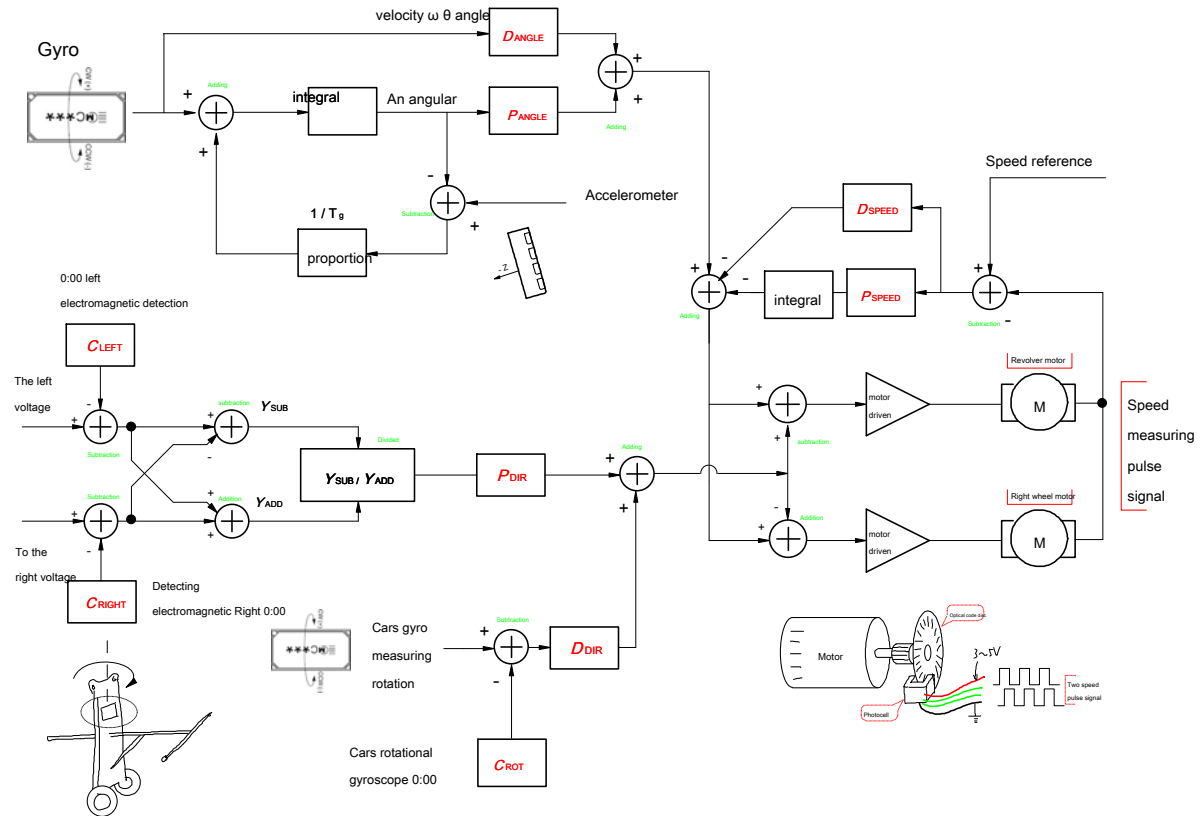

Map 2-40 Motion general block diagram Cars

Map 2-40 Or maintained in the gravitational acceleration sensor, in complete control of car models, which can be controlled by the speed

Partial replacement system.

To achieve the upright car models to be collected the following signals:

(1) Cars velocity gyro angle signal, and the angular velocity obtained inclination car models.

(2) Gravitational acceleration signal (z Axis signal), the gyro drift compensation. The signal can be omitted, the speed

Control instead.

(3) Cars motor speed pulse signal obtained Cars velocity, speed control.

(4) Cars electromagnetic deviation signal (two-way) to obtain a positional deviation from the center line of car models, the direction control

system.

(5) Cars gyro rotational speed signal, the steering angular velocity obtained Cars, directional control.

The above signal acquisition can be simplified and the signal out of the gravitational acceleration Cars rotational speed gyro signal.

Cars upright control, speed control and direction of the three links are used proportional differential (PD)control,

The three final output of the control algorithm is done by superimposing motion by a motor.

(1) Cars upright control: inclination car models PD (Proportional, derivative) control;

(2) Cars speed control: PD (Proportional, derivative) control;

(3) Cars direction control: PD (Ratio, differential) control.

The control algorithm may be implemented by the microcontroller software.

After the above control process, the control and direction of the angle control car models are superimposed on the output voltage direct electrical control

Machine speed achieved. Cars and speed control by adjusting the angle of inclination is essentially implemented car models, car models is due

A non-minimum phase system, and the feedback proportional control if the speed is too large, it is easy to form a positive feedback, so that

Cars out of control, resulting in instability of the system. Therefore, the adjustment speed of the process requires very slow and smooth.

The control block diagram schematically illustrate only the control relationship. In the software implementation process, also taking into account the need to

A collection volume ratio of the polar and the zero point value and the signal. In Fig. 2-40 In the directional control has been added zero

Correction process. The same procedure for controlling the angle of gyroscope and accelerometer acquisition channels need be. Signals

Cars circuit design a control system, firstly the need to analyze the system input and output signals, and then select the appropriate

The core embedded control computer (SCM), circuit design of each sub-module gradually, and finally form a complete electrical control

road.

Input and output system comprising:

（1）AD Conversion interface (at least 5 road)

a) Electromagnetic detection: two left, two right and left induction coil for measuring the voltage.

b) Gyro: two-way. Cars for detecting the inclination angular velocity all the way, the way for detecting a rotational angular velocity Cars

degree.

c) Accelerometer: one measuring acceleration Z Axis output voltage.

d) Assisted debug :(spare) 1 To 3 Road, Cars for debugging, setting role.

（2）PWM interface(4 road)

a) Control electrodes around two sides to run. Since the unipolar PWM drive requires four PWM

interface. If bipolar PWM driver, two may be used.

（3）Timer interface (2 road)

a) Two measuring motor speed, timer pulse requires two input ports.

（4）Communication interface (standby)

a) SCI (UART): One for program download and debug interface;

b) I2C Alternate :() If Freescale digital accelerometer, can I2C Direct Interface

Then reads acceleration values.

（5）IO interface (spare)

4 To 8 Input Output, status display application running car models, function settings and the like.

Said interface, the gravity acceleration sensor and a gyro rotational speed car models may be simplified omitted.

Competition allows the use of Freescale's processor family, the vast majority are able to meet the control requirements above.

Reference in the present embodiment selection Freescale DSC 16 Bit processor MC56F8013 As the core of the control processor

Design. Cars overall block diagram of a control circuit in FIG. 3-1 Fig.
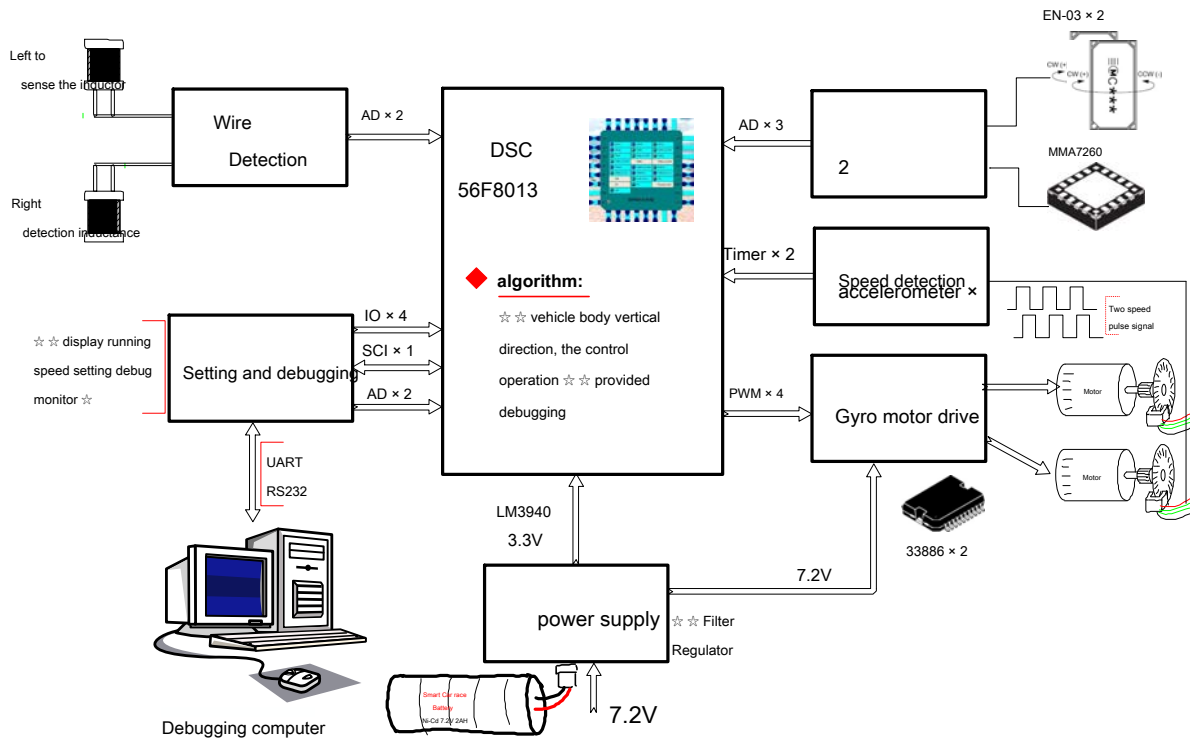

Map 3-1 A control circuit block diagram of the overall upright Cars

According to FIG. 3-1 The control circuit is divided into the following sub-modules:

(1) Smallest SCM system: comprising DSC Processor, download the program debugging interface;

(2) Magnet wire Detection: comprising two identical amplifying the electromagnetic induction signal detection circuit;

(3) Gyroscope and accelerometer: attitude sensor signal amplifier comprises three filtering circuit;

(4) Speed detection: detection photoelectric encoder motor pulse frequency, in fact, only the sensor comprises two photoelectric encoder of

    Device. ;

(5) Motor drive: two electrodes operating power driving circuit;

(6) Power: the power supply voltage conversion switch, voltage regulator, a filter circuit;

(7) Set and Debug: displays system status, speed setting, download and monitoring.

  We are given below with reference to design the circuit of the above embodiment.

3.2 DSC Introduction and smallest single-chip system

So that the motor speed sensor Used in fixed optical encoder of the motor output shaft and on the photoelectric device cooperating

Element, FIG. 3-10 Fig.
Map 3-10 Speed sensor circuit

Since the pulse signal is directly output digital photocell device, can be connected directly to the pulse signals monolithic

Machine counter port.

Each phototube outputs two pulse signals which are the same waveform, but out of phase 90 °. If the motor is transferred,

The second pulse behind 90 [Deg.]; If reverse, the second pulse lead 90 °. This relationship can be judged by

Whether reversing the motor. In the actual circuit, only one pulse signal is detected, the motor obtained by measuring its frequency

Speed. A steering motor is determined by applying a negative voltage to the motor. Although the existence of inertia Cars

In possible at low motor speed, the rotational direction of the motor and the voltage applied to its positive and negative may be different,

Causing the inaccuracy motor speed. As the racing game game, in general, the motor is running at high speed like

The state, the steering direction and the motor voltage is the same. Experimental verification by this method can effectively determine the motor

Rotational direction and speed control.

3.6 Wire detecting circuit

(1) Discrete components amplifying electromagnetic detector circuit

Wire road centerline detection is to ensure car models capable of running on the track. Since the electromagnetic group in the fifth race

It has been set up, in 2010 In the competition secretariat published a reference design magnet wire detection. Detailed design principles

See reference circuit and appendix.

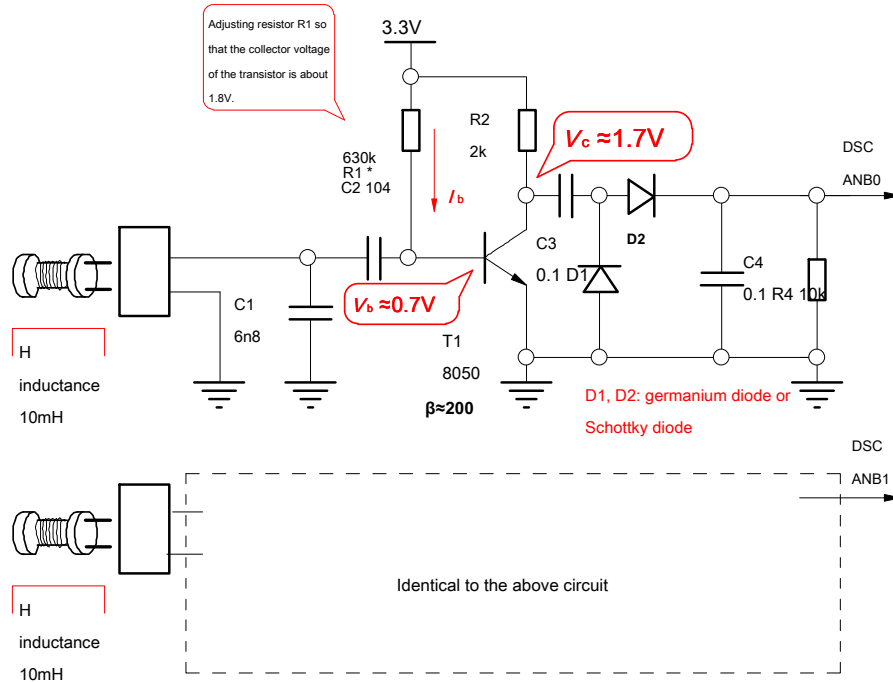

Map 3-11 Detector circuit based on an electromagnetic signal amplifying transistor

In order to ensure that the signal amplifying transistor amplifier dynamic range is large enough, the collector of the transistor need to be

In about half of the pressure regulating circuit voltage: $3.3 / 2 = 1.65 = V_c$. This requires the base of the transistor by adjusting a bias electrode

In resistors R_1 Completed. The R_1 value may be calculated from the formula: $R_1 = \dfrac{V_{cc} - V_b}{I_b} = \dfrac{V_{cc} - V_b}{I_c / \beta}$ Wherein the collector current

$I_c = \dfrac{V_{cc} - V_c}{R_2}$. The circuit parameters into the computer can be obtained $R_1 = 630 \ k\Omega$.

According to the above circuit diagram of the circuit fabricated as shown in FIG 3-12 Fig.
Map 3-12 Electromagnetic amplification transistor based physical map detector circuit

(2) Integrated operational amplifier amplifying an electromagnetic detector circuit

Amplifying triode electromagnetic detector circuit is simple and practical, it has been widely used in the game. If you need to enter

Further improve the sensitivity of detection may add a transistor amplifier. Using discrete components triode

Amplifying detector circuit has some drawbacks:

(1) To adjust the operating point of the voltage is complicated;

(2) Depends on the magnification circuit transistor current amplification factor and base-resistance, etc., more dispersed;

(3) Due to the forward voltage of the detection diode for the detection can not be performed very weak electromagnetic signals.

An integrated circuit can be simplified amplifier design, improve the performance of the circuit. Based on the output is given below

Full voltage range (Rail-to-Rail, Electromagnetic rail to rail) amplifying operational amplifier detector circuit.

RR Amplifier generally operates in a single power supply, the output voltage range substantially close to the supply voltage and ground.

Map 3- 14 LMV358 Amplifying the detection output waveform

The figure is based on LMV358 FIG detector circuit amplifying two physical channels electromagnetic induction design.

Since the operational amplifier common mode input voltage range may be less than 0V , So that the weak signals for a circuit with a very good

The amplification and detection performance. Magnification is determined by the feedback resistor circuit network, stable. Since the detection field

Direct access to the resonant circuit inductor positive input terminal of the operational amplifier, very high input impedance, thereby improving the product of the reso

The quality factor (Q Value), such that the input frequency selection capability greatly enhanced.

Since the half-wave detection signal when the output signal, the maximum value of the output signal does not exceed half of the power operational amplifier.

In order to improve the dynamic range of the signal amplifying circuit voltage of the op amp is selected 5V .

Since the frequency of the signal is 20kHz So choose RR Op amp's unity gain bandwidth must be large enough, this

For samples in order to ensure 20kHz Signal amplification capability, it is recommended operational amplifier unity gain bandwidth greater than at least 1MHz .

3.7 Angle calculation circuit

In principle, there are two control car models car models described in chapter angle and angular velocity measurement method, by first gyroscope

And an acceleration sensor device is achieved, the second may be achieved by two acceleration sensors. After the angular velocity feedback

Points can obtain a smooth angle signal coincides with the acceleration sensor. This signal processing section may be performed by the microcontroller

Software to complete the operational amplifier circuit may be implemented by an external. This section shows that part of the signal processing circuit implementation

formula.

(1) Was calculated from the acceleration sensor an angular velocity double

according to 2.3 Cars introduced angle measuring section, mounted on the top and bottom of the car models two acceleration sensors

MMA7260 of Z Axis signal through subtraction, it is possible to obtain the angular acceleration of the car models. This signal can be integrated

To obtain an angular velocity of car models. Map 3-16 It shows implementation of.
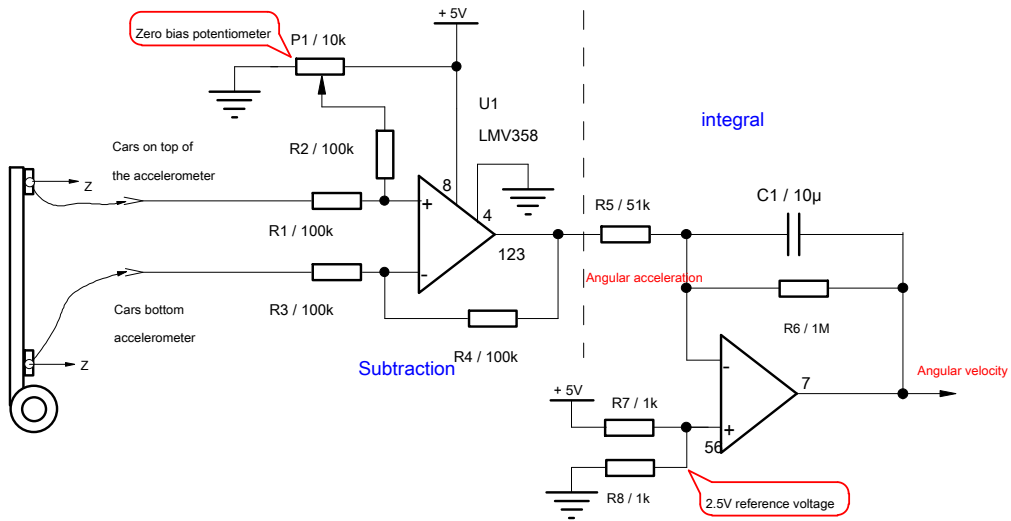

Map 3-16 Double angular velocity acceleration measurement circuit

The above circuit diagram consists of two parts, first part is to achieve signal subtraction to obtain the angular acceleration of the car models. The first

The second part is integral calculation to obtain the angular velocity of car models. The figure is a waveform diagram of the actual signal.
Map 3-17 Dual accelerometer waveform diagram measured angle

In order to verify the performance of the circuit, FIG. 3-17 Also mounted on the simultaneous acquisition of car models ENC-03 The measurement signal.

As can be seen from the waveform of the wave angular velocity obtained by the acceleration sensor and the angular velocity of the car models integrating gyro meas

Shape is the same, the method is validated.

To further simplify the circuit, the acceleration sensor may be mounted on top of car models reverse, so the top of the sensor

Device Z Variable axis signal and then the bottom of the acceleration sensor signal symbol contrast, as long as the two overlapping signals through a resistor

Together subtraction signal can be realized, whereby the circuit can be further simplified as 3-18 Fig.
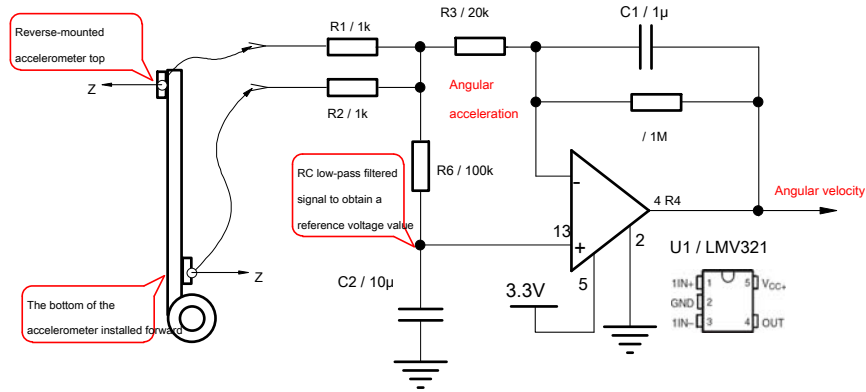

Map 3-18 An angular velocity simplified circuit

Map 3-24 different P1 Output waveform corresponding to the resistance

According to the previous design, the angle of measurement and signal processing can be combined to form a unified to simplify the circuit. Figure

3-25 Fig. The circuit may output the angular velocity values and the angle of car models. Angle signal through hardware processing,

You can simplify programming and debugging, improve software reliability, speed up the process of making car models for beginners. So this part

Cars circuit for beginners.
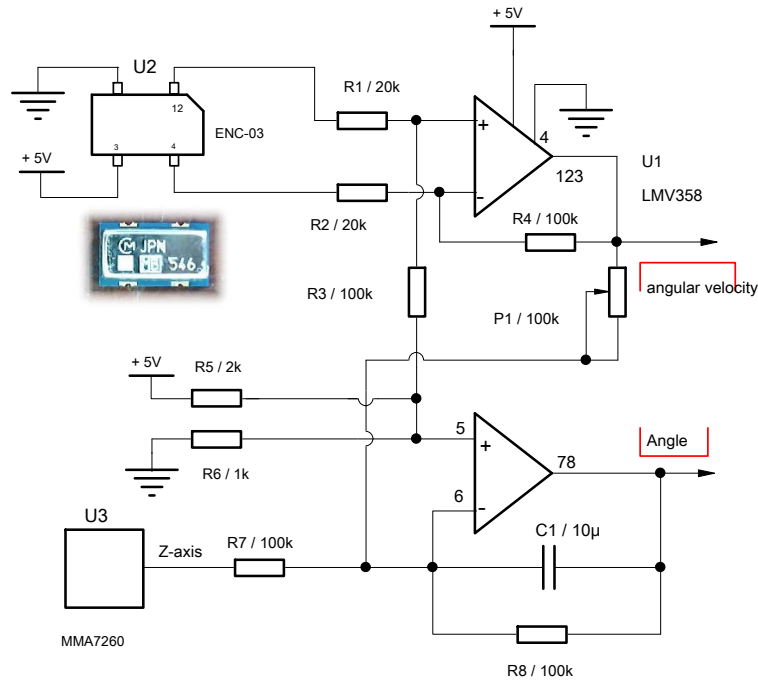

Map 3-25 Simplified processing circuit angle and the angular velocity

Circuits through the above parts actually, the upright may be achieved in the control of car models.

3.8 Cars full control circuit of FIG.

Summary circuit design of the various parts of the front, the final selection of a full car models control circuit shown in Figure 3-26 Fig.
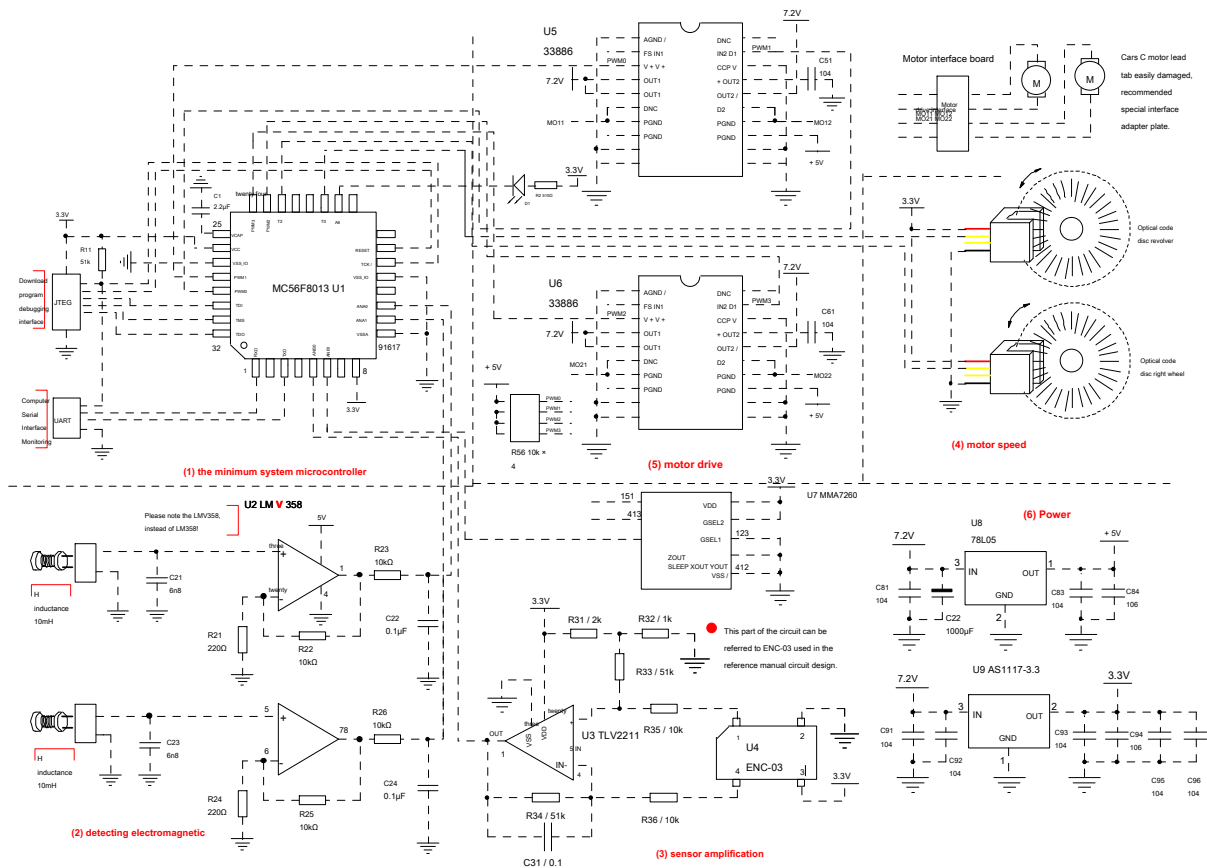

Map 3-26 Cars full control circuit of FIG.

The control circuit includes a digital circuit and an analog circuit, a small signal circuit and power circuit. When designing a circuit board,

All integrated circuit may be implemented in a circuit board, the block can be broken down into several circuits were produced. From circuit

Schematic design of the circuit board, not only the attention of the logic function circuit board traces, the circuit board also need to consider cloth

Line, to prevent mutual interference between the various parts of the circuit, the circuit to ensure stable and reliable.

Not related to the debug circuitry associated with the above circuits, the following debugging in fact used to

Microcontroller serial port, the other two AD Input port (ANA2, ANB2) And other resources. We can according to their own

The commissioning program design is complete contents of this section

Map 3-26 Angle calculation circuit circuit is not for angle measurement part is performed by the internal microcontroller software.

Above gives the main control circuit of the circuit design of car models, in addition to the need to design a power management circuit, parameter setting

The monitoring circuit is set, and operation program debugging interface circuit. Students can contest the previous technical report in accordance with

Off design.

56

The fourth chapter, mechanical design articles

Good mechanical design and production of car models, car models for stable operation, security debugging is very important. As far as

Cars simplify modification and the sensor mounting two aspects discussed.

4.1 Cars simplify modification

Since this year, the original use of the electromagnetic group race car models C Type of car models, which is a two-wheel drive, front wheel steering servos

Sport mode, and competition regulations C Cars upright type, so the front car models and some associated components may be

simplify. Specific reference to the following modified steps:

(1) And remove the front wheel support member, a buffer to remove the rear wheel suspension bracket

Where disassembled as shown in FIG.
Map 4-1 complete C Type chassis Cars
Map 4-2 Simplified C Type chassis Cars

(2) Fixed to the chassis and the rear wheel bracket Cars

In order to alleviate the existing car models rear impact vibration of the vehicle body, using a movable connecting between the bracket and the rear wheel cha

Access way. However, to ensure the stability of the vehicle body upright car models, it requires the original car models with the rear wheel bracket to the site

together. The most convenient way is to use hot melt adhesive at the gap between the rear bracket and the chassis are bonded. This

Between the vehicle body and the wheel-like forming a rigid, upright facilitate control. Map 4-3 It shows the position of the hot melt adhesive.
Map 4-3 And hot melt adhesive used to fix the motor car models chassis bracket

(3) To remove the rear wheel, the motor speed ready to install an optical code disc

Removable rear cross socket wrench can be used with the original car models. FIG disassembled Cars 4-4 Fig.
Map 4-4 After removing the rear wheel chassis Cars

In Fig. 4-4 Please note that the use of hot melt adhesive fixing bracket and the rear wheel chassis car models.

After installing the speed sensor, and then again two rear wheels mounted to the rear bracket.

Please note that the rules of the game change for car models chassis limitations do not allow the use of other materials into the chassis for Cars

Line larger changes.

(4) Reinforced motor lead

C Cars rear wheel motor lead pin is very thin, easily broken after repeatedly shaking from the roots, causing no motor

Method to use. It proposed to add a motor adapter plate, welding the first lead of the motor adapter plate and the adapter plate solid

It does not cause breakage of the motor lead when held on the motor car models or scaffold floor, disassembly of such a circuit board.
Map 4-5 Motor lead adapter plate

Of course, the composite may be used as hot melt adhesive or glue for fixing the motor lead pin encapsulation, may be

It can protect the motor leads.

Further, the metal shaft coaxially with the drive motor in fact there is not much effect, if the installation for other purposes

You can also remove them.

4.2 Sensor Installation

Cars in the sensor comprising: a speed sensor, an attitude sensor Cars (gyroscopes, accelerometers) to

And detecting an electromagnetic induction coil. The following describes the installation of these sensors.

(1) Speed sensor mounted

The speed sensor is mounted on the output shaft of the drive motor and optical encoder for cooperating photoelectric tube. Fixed light

Code disc may use composite glue, the plastic shaft the output shaft of the motor photoelectric encoder adhesive. Figure 4-6 Fig.
Map 4-6 Composite glue fixed optical encoder disk

After bonding code disc, and then fixed on the photoelectric detector. The hot melt adhesive may be used on the photoelectric fastened to the rear bracket

Fixed photoelectric tube, such that the optical encoder of the intermediate tube by a gap. Figure 4-7 Fig.
Map 4-7 Good fixing photoelectric encoder and the photodetector tube

Please note that the fixed code disc must be better use of the thermal stability of the composite glue, such as "two brothers." due to

Motor heat during operation, and the large vibrations, so do not use hot melt adhesive fixed code disk.

After completion of the above-described fixed speed sensor, a rear wheel can be re-mounted to the rear bracket.

(2) Electromagnetic sensor mounted

An electromagnetic sensor of the present embodiment designed for the two I-shaped 10 MH inductance. In order to better detected before

Road surface, generally the two I-shaped inductance as possible installed in front of the local car models run farther. due to

Cars run upright, the program may be considered as follows with reference to FIG. 4-8 Fig.

Physical installation
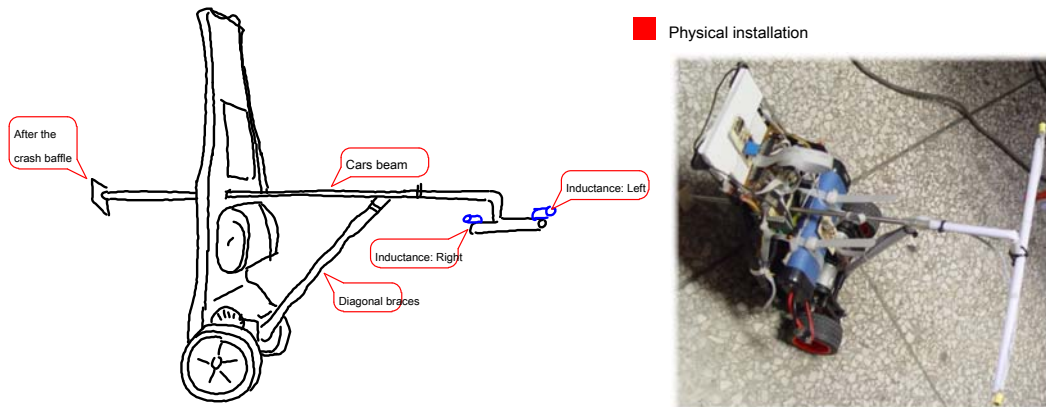

Map 4-8 Electromagnetic sensor holder

Please note that the competition rules to limit the dimensions of the car models. Since the tournament only limits the width of the car models,

To less than 25 cm. For Cars no length and height restrictions.

Because the tournament does not require car models automatically stop at three meters on the track after the race finished after its implementation, and there

Without detecting the starting line of the permanent magnet track.

To avoid the influence of car models by crossed lines through the mouth, the two induction coils fixed time,

Try to keep the two coils in a horizontal position, and in a straight line, as shown below.

Map 4-9 An electromagnetic coil mounted horizontally

If the electromagnetic coil is mounted not on the same horizontal line, then the cross car models when crossing an intersection, the level of

In the wire direction of the magnetic field induced electromotive force is generated on the additional two coils. The electromotive force will cause the car

Direction control mode instability.
Map 4-10 An electromagnetic coil mounted not on the same horizontal line

Since the electromagnetic coil at the forefront of car models, we ran out of control track car models after striking other objects were first

An electromagnetic induction coil is broken. In order to protect the electromagnetic induction coil, such that they can at the same time in a horizontal linear

Line, can be used hard plastic tube solenoid packaged together. As shown below:
Map 4-11 Plastic pipe with a hard package electromagnetic induction coil

If more than two magnetic detection coil, also conceivable to use other bracket way to increase sensor

Strength of the stent.

(3) Cars tilt sensor

Cars tilt sensor includes a gyroscope and an accelerometer. They are surface-mount components, generally fixed at the same potential

Road board. The board is recommended with a gyroscope and an accelerometer fixed in position throughout the middle car models centroid,

Or bottom of the car models, thus reducing interference with the measurement by vibrating the inclination Cars run maximally.

Should try to ensure that when a gyro sensor is mounted horizontally mounting angle of the sensor circuit board.
Map 4-12 Horizontal mounting gyroscope

If the gyro installation is not able to guarantee the level, it will affect car models over speed corners. The performance of car models in the past

When the curve becomes faster or slower speed. Analysis has both car models such that movement in the corners, the corners in Cars

Motion: translation and rotation. Which will lead to the rotation gyroscope rotation. If the gyro installation is not the absolute level, that

What will be in the rotation gyroscope Z There is a component of the axial direction. According to the gyro different inclination, this

There may be a positive component, there may be negative. Cars will be controlled so that the "feel as if the uphill or downhill"

Causing slow speed car model or faster.
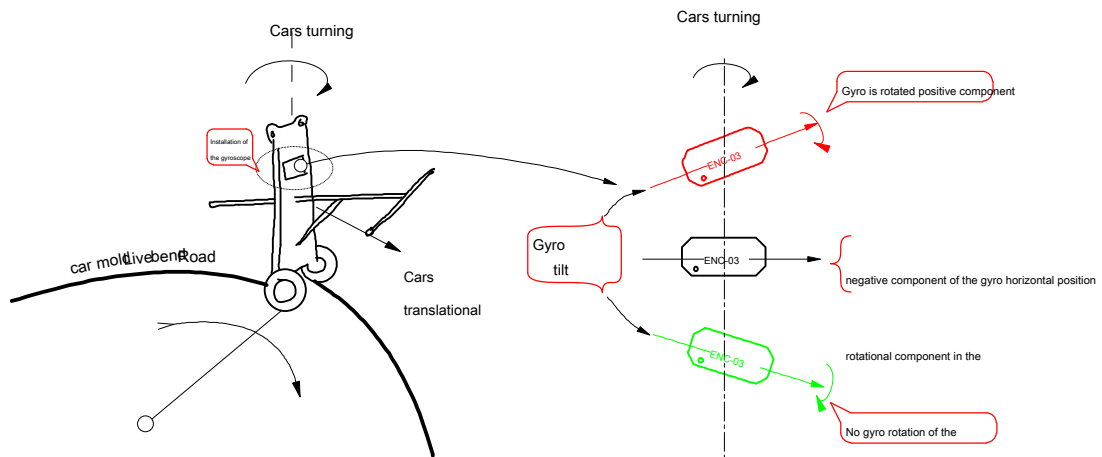

Map 4-13 Cars influence gyro installation angle the corners

4 , Steering speed gyroscope Cars

Cars steering speed sensor is used to control the differential direction, a direction to eliminate the overshoot control.

The gyroscope rotation shaft and a vertical longitudinal axis gyroscope requires consistent. If the steering does not require car models

Differential control, then this sensor can be omitted.

4.3 Precautions

Cars run since the upright, in the production of a circuit board to reduce the size of the circuit board as far as possible, on the one hand to facilitate solid

Set, on the other hand can reduce the inertia of car models.

Fixing the circuit board to be close to the chassis as car models, it is possible to secure.

In order to avoid during the pouring operation Cars, Cars and broke the circuit board, when in the mechanical design of car models,

Cars need to be considered before and after the mounting bracket or the anti-collision cushion, once out of control or dump car models, the stent may crash

To protect the safety of car models machinery.

In addition, the car models may be mounted on the fall collision detection switch holder, once poured car models, the control circuit will be established

That is, stop running. Wireless remote control switch may also be used, such car models can emergency brake, thereby avoiding runaway due Cars

Impact damage. Map 4-9 Shows a case where the reference test design after assembly of car models.

Chapter V, software development articles

By the foregoing description, the control circuit production and installation of car models have been completed. Cars whether the normal high-speed stability

Run, you need to control the software debugging and car models by writing to complete. The main tasks include the development of software:

(1) Established software engineering, configuration DSC Resources, the preparation of the preliminary program of the main frame;

(2) The preparation of PC monitoring software, build software to compile, download, debug environment;

(3) Prepared to achieve each sub-module, and test the functional correctness of each sub-module;

(4) By the initial debugging program, verify the correctness of the control circuit board.

Freescale Development 56800 / E series DSC SCM application can use CodeWarrior integrated

Development environment (CodeWarrior for 56800 / E Digital Signal Controllers , The current version v5.9). And other

Version of CodeWrrior same, DSC Version CodeWarrior Also provides Processeor Expert Function modules,

To produce a microcontroller through project configuration is very easy to various peripheral initialization code and interface program to help develop

It will focus on application development.

5.1 Software function and framework

The main features of the software include: (1) Acquiring

sensor signals, the process;

(2) Motor PWM Output;

(3) Cars run control: vertical control, speed control, direction control;

(4) Cars run process control: program initialization, start and end car models, car models status monitoring;

(5) Cars display setting information and parameters: status display, PC monitor, parameter settings and the like.

The above-described functions may be divided into two categories:

The first category includes 1-3 Function, they are in need of precise time period of execution, a timing cycle can be

Interruption in the completion. The second category includes 4-5 Features. It does not require precise execution time period. It can be placed in the program

The main program is completed. We can communicate with each other through the global variables between these two types of tasks.

The main program frameworks such as **error! Reference source not found.** Fig.
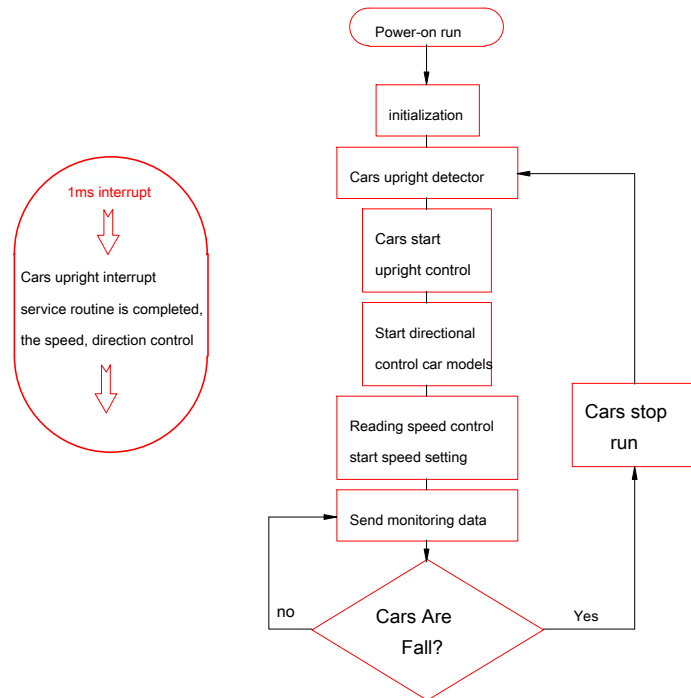

Map 5-1 The main program framework

error! Reference source not found. After, the power to run the program, then initialize the microcontroller. Initialization work

It comprises two parts, one for each application to initialize the module microcontroller. This part of the code consists of

CodeWarrior Integrated Environment ProcessorExpert Tool generates. The second part is the application initialization is

Cars in the application to the control program values of variables are initialized.

After initialization, the upright first enters Cars detection subroutine. The program read by the accelerometer value determination

Cars off is in an upright state. Once in the upright position if the starting upright Cars control, direction control, and

speed control.

Continuously monitoring data transmission program in the primary cycle, is sent to the host computer through the serial port is monitored. Also check

Cars whether the fall. Fall can be determined by determining whether the tilt angle exceeds a certain range of car models, or by mounting

Cars before and after the micro switch holder on a collision is determined. Cars must fall, stop the car model run. Including Cars

Vertical control, speed control and direction control. Then re-enter the car models upstanding determination process.

Car models upstanding control, speed control and direction control is done in the interrupt program. By global flag change

Determine whether the amount of these closed-loop control.

Interrupt program framework shown in Figure 5.2 Fig.
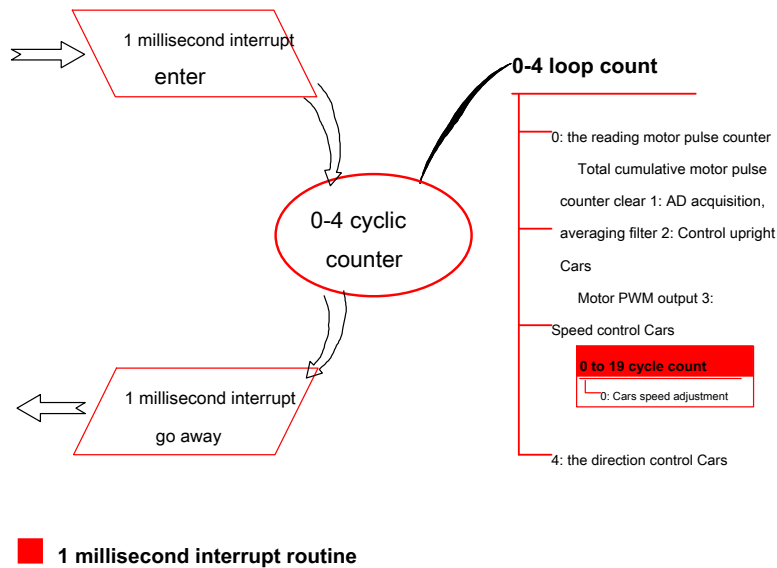

Map 5-2 Interrupt service routine

Map 5-2 Using DSC A timer, generating a millisecond periodic interrupt. Interrupt service routine tasks

Is uniformly distributed 0-4 It interrupts fragment. So each cycle interrupt task execution segment is 5 Ms, frequency

Was 200Hz .

The task assigned to different interrupt segment, on the one hand to prevent the accumulation of these tasks take longer than 1 millisecond,

Disrupt a millisecond timing interruption, while also taking into account the time between the order of these tasks. Of course, it can be the

Some interrupt tasks are combined, using a 5 Ms interrupt to complete.

These tasks include:

(1) Reads the motor speed pulse counter cleared. Cumulative motor rotation angle. Cumulative motor speed, after

Cars speed control provides the average surface;

(2)start up AD Conversion. get on 20 Analog acquisition times, and calculates an average value of each analog channel.

This process is carried out for the low-pass filtered analog signal.

(3) Cars upright control process. Cars angle calculation includes upstanding control calculation, the motor PWM Output.

(4) Cars speed control: in this time segment, and for 0-19 count. In the first of 0 Fragment,

The speed PID adjust. Thus, the speed adjustment period 100 millisecond. That is per second adjust 10 Times.

(5) Cars directional control: electromagnetic field detector read previous value, a deviation value. Then calculate

Motor control voltage differential value.

Each of these interrupt tasks occupy different time, when the program debugging, need to ensure that they are not more than 1

millisecond. Each specific task execution time can be displayed by the microcontroller ports. As it is through the microcontroller

led Control port A6 , Showing each task execution. Upon entering the interrupt, A6 High output, launched

Interrupted, A6 Output low. Figure 5-3 Waveform shown in FIG.
Map 5-3 Task interruption time waveform

Each task can be time consuming task from above interruption time waveforms:

table 5-1 Interrupt task execution time table

time Fragments	Task execution time (Microseconds)	mission name	Remark
1	110	Pulse rate	

2	720	AD Change	Conducted 20 Times 6 Analog Channel acquisition and averaged.
3	430	Cars angle control	
4	90	Cars speed control	Speed control period is 100 Hair second.
5	150	Cars directional control	

Quit after an interruption, the main program execution, monitoring and debugging run to complete the car models.

5.2 DSC Hardware resources

The following describes the procedures used DSC The module resources and their configuration. If other family of processors,

Referring to these configuration settings.

1) Ms timer interrupt: TI1

Hardware modules: TMR2_Compare

Any comments should be very clear.

5.3.2. The main control Function Description

This section will explain the main control functions. The function code in general are used C Language, single-precision floating-point operations.

Easy for beginners to understand and transplantation.

1. AngleCalculate : Angle calculation function

This program reads DSC of AD Numerical, and then calculate the tilt angle of the car models.

Values for gyroscope and accelerometer bias reading was subtracted value. This value need to be determined experimentally

set. Cars upright when stationary, the read values of the two channels, is the corresponding bias value. This value will take

There are some errors, such car models tend acceleration traveling in one direction. This error can be controlled by the speed of the latter

System to eliminate them.

For the accelerometer values obtained by a scaling factor (GRAVITY_ANGLE_RATIO) It

Normalized to - 90 to 90 Between this macro definition header file please everyone to read the project file. Similarly, the back of the Tuo

Spiro meter read data needs to be normalized by a scaling factor. This value is determined by experiment

of. Specific ways to see the back of the debugging process.

Due to the time period of this function call 5ms . Detailed procedures, see the program - 1 Code:

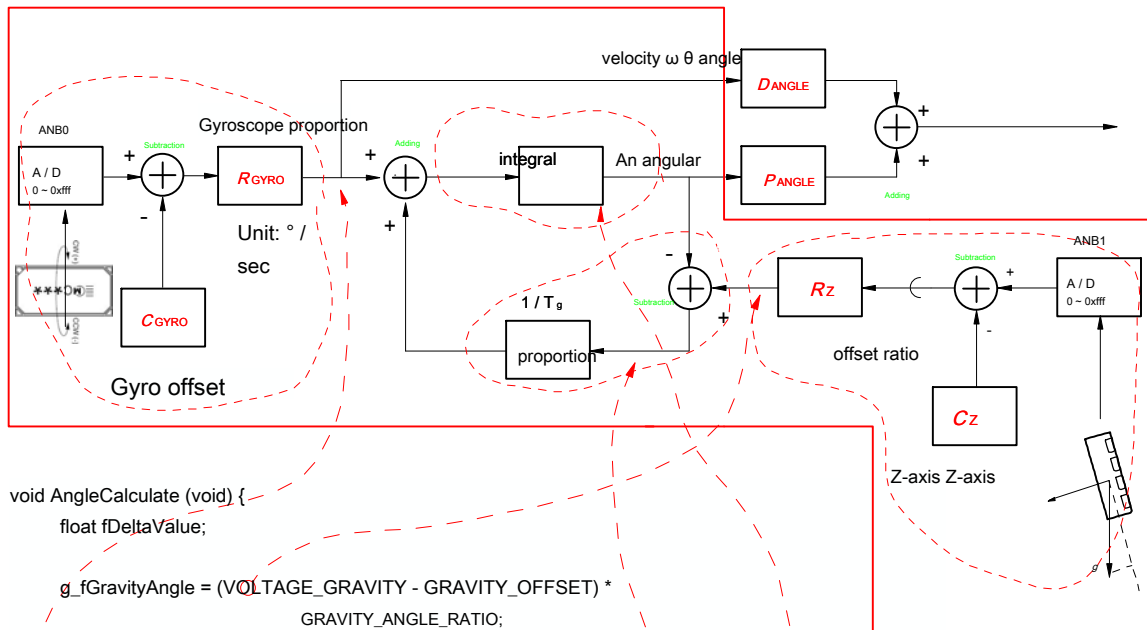

```
void AngleCalculate (void) {
        float fDeltaValue;

        g_fGravityAngle = (VOLTAGE_GRAVITY - GRAVITY_OFFSET) *
                        GRAVITY_ANGLE_RATIO;
// g_fGravityAngle = 0;

        g_fGyroscopeAngleSpeed = (VOLTAGE_GYRO - GYROSCOPE_OFFSET) *
                        GYROSCOPE_ANGLE_RATIO;

        g_fCarAngle = g_fGyroscopeAngleIntegral; fDeltaValue =
        (g_fGravityAngle - g_fCarAngle) /
                        GRAVITY_ADJUST_TIME_CONSTANT;

        g_fGyroscopeAngleIntegral + = (g_fGyroscopeAngleSpeed + fDeltaValue) /
                        GYROSCOPE_ANGLE_SIGMA_FREQUENCY;
}
```

program - 1 Angle calculation function

Worthy of note is the angle calculation function can be performed by hardware, see Figure 3-25 Simplified angle and angular velocity

Of the processing circuit, which can help us further understand the perspective of processing algorithms. If the actual circuit employed in FIG.

3-25 Program, this angle calculation function can be omitted, can be obtained directly by collecting the corresponding angle of Cars

And angular velocity.

Speed control period 100 millisecond. Reading two electrodes optical encoder pulses accumulated by 100 Ms

It may reflect the number of pulses of the rotational speed of the motor car models. Cars using the average speed of the two electrode velocity.

In order to make a speed having a physical meaning, the obtained value for the motor speed required for the unit conversion.

The physical meaning of the definition of the unit, the unit can determine the speed ratio of conversion values. In this procedure, the speed of the defined

A motor unit number of revolutions per second. Thus the ratio of the unit value (CAR_SPEED_CONSTANT) defined as:

```
#define OPTICAL_ENCODE_CONSTANT 100 // Number of notch optical encoder disc

#define SPEED_CONTRO_PERIOD              100 // Speed control cycle, ms

#define CAR_SPEED_CONSTANT               // Scale value conversion unit

        1000.0 / SPEED_CONTROL_PEIORD / OPTICAL_ENCODE_CONSTANT
```

To reduce the impact on the speed control car models upstanding control, the speed control is a function of the amount of change of the output

SpeedContorlOut Uniform distribution 20 The function of angular control period, which can ensure the stability of the car models.

```
void SpeedControl (void) {

Chapter VI, scale models debugging articles

Cars production and software development for the car models running the foundation, is running stable and rapid needs by car models

Careful commissioning to complete. Debugging process also can make students deepen control algorithms for physical processes deep

Engraved understanding, improve the ability to solve practical engineering problems, to find a basis for a more optimized design of car models. Tone

Trial process is very important for the race car model production.

Cars are divided into Debug debugging preparation, the static parameter tuning, dynamic tuning parameters, scale models and competition policies mechanic

The development of other links. Relates to the entire debugging parameters and components are very large, and there is a tight between these parameters

Interaction dense. If the physical process in which the clear understanding that there is no proper commissioning steps, then tune

Various errors phenomena that occur during the test will cover up for the right reasons, affect the entire commissioning process, and even shake system

For confidence.
Map 6-1 Cars debugging complex and critical parameters

This section describes the steps Cars tuning parameters as a reference.

6.1 Debugging parameters

Algorithm program exists many parameters given above, although the calculation of these parameters may be optimized in theory.

However, due to the impact accuracy of the model car models, the resulting calculated parameters may also be used as a reference value only - Commissioning

Starting range. The actual optimization parameters required by certain steps to finalize the project, this process is called parameter tuning.

First determine the required control parameter tuning car models. In the appendix 5 A block diagram of the control algorithm is given, all the required

Tuning parameters are marked in red. These parameters include two categories:

1 , Sensor parameters:

R_{GYRO}: Gyroscope scale. The gyroscope AD An angular velocity signal values into the acquisition unit is ° / sec.

C_{GYRO}: Gyroscope zero offset. When the gyroscope tranquility AD Collection volume.

C_Z: Gravitational acceleration Z Axis zero offset. When the accelerometer is stationary vertical Cars AD

Collection volume.

Z_{MAX}: Gravitational acceleration Z Axis maximum acquisition value. When the back-up Cars Z axis AD Acquisition value.

Z_{MIN}: Gravitational acceleration Z The minimum acquisition value axis. When the front car models up Z axis AD Acquisition value.

C_{LEFT}: The left side of the electromagnetic induction coil zero offset. Externally 20kHz When the power is turned off, the left electromagnetic induction

Coil should channel AD Acquisition value.

6.2 Debugging condition

Cars assembled after installation, before the formal commissioning I need to prepare conditions:

1 , Scale models circuit initial commissioning: a power control circuit may correct, the microcontroller can download the program.

2 , Scale models debugging environment: the site must be debugged and auxiliary car models 20kHz Power supply.

3 , Hardware and software debugging aid Cars: Cars sport protection and parameter monitoring software.

The above conditions can be made in the development of car models, debugging process gradually improved. The following describes these debugging

Requirements and readiness conditions.

6.2.1. Cars preliminary circuit debugging

Cars preliminary circuit debugging lay the foundation for the back of the car models software parameters. Comprising five basic steps, namely

Introduced. :

1 , Check the power supply

Plus circuit 7.2V After the battery voltage, the output value of the operating current measurement circuit and the voltage regulator circuit whether each

Within a safe range.
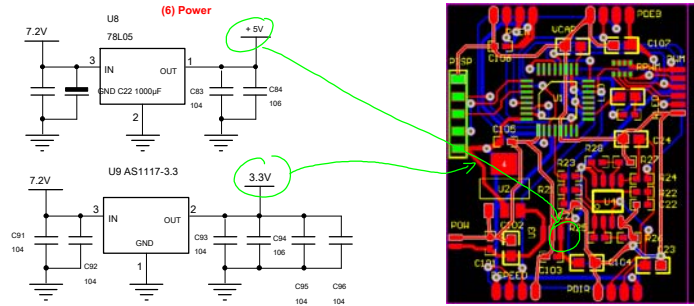

Map 6-4 Check the power supply

Reference circuit design comprises 7.2V , 3.3V , 5V Three power. When static, the total power supply should work

in 150mA about.

2 , Microcontroller program download and communication:

Desktop sensor parameters comprising static parameters and control parameters in the stationary state of the car models tuning.

6.3.1. Sensor parameters

Cars sensor measurement parameters include motion states of the respective car models car models stationary sensors at zero offset to

And the proportion of unit conversion values. In Fig. 5-15 These parameters will be marked out.
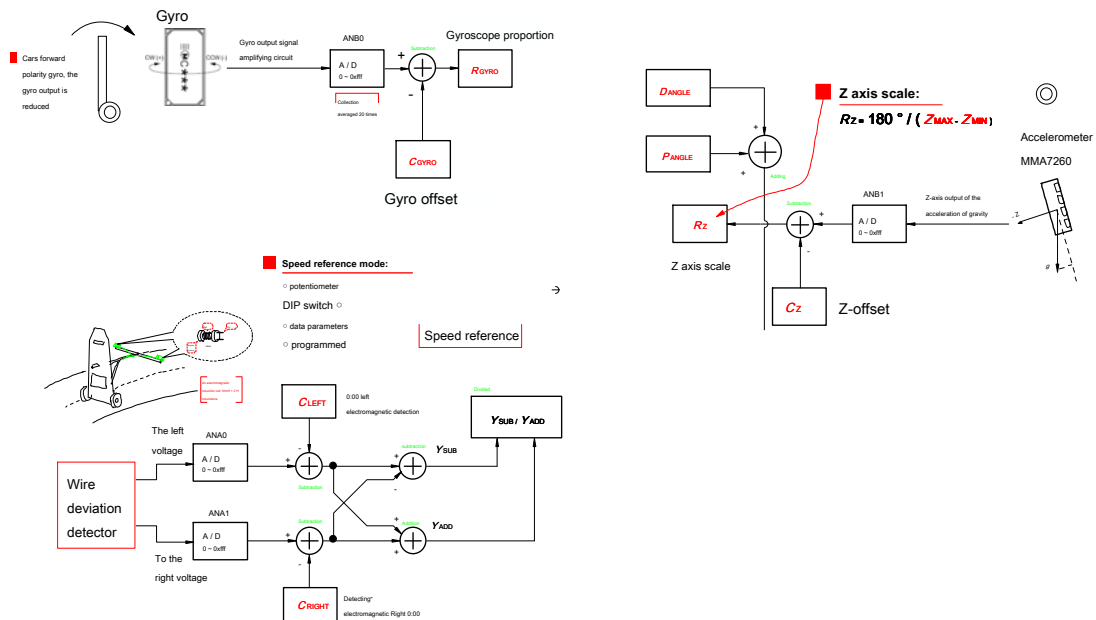

Map 6-15 Setting sensor parameters required

1 Measuring transducer zero offset

Debug table, holding Cars vertical stationary state, closed 20kHz Electromagnetic power supply. By SCM software acquisition

Each analog channel AD Value passed to the host computer for display. Determining the zero offset for each sensor:

$$C_{ANGLE}, CZ, C_{LEFT}, C_{RIGHT}, C_{DIR}.$$
Map 6-16 Cars held vertically stationary

The average multiple acquisitions can be obtained by a more stable and accurate. In the reference embodiment, the acquisition of 1024 Times each through

Channel average value as the zero point offset amount of the respective channels.

2 Measuring an acceleration sensor Z Axis maximum, minimum

Cars held stationary side up and tails can be measured Z Maximum and minimum axes.
Map 6-17 Measuring acceleration sensor extremum

Maximum and minimum values of the acceleration sensor may be used to determine an acceleration sensor Z Ratio corresponding to the angle of the shaft

value: $RZ = \dfrac{180}{Z_{MAX} - Z_{MIN}}$. This ratio may be accelerated by the sensor Z Axis signal into an angle signal,

The unit is degrees.

3 , Gyro scale value calibration Cars

The scale determines the R_{GYRO} gyro angular rate gyroscope unit obtained by integrating a degree of acceleration of gravity and mass

Sensor is the same. This ratio can be calculated by the formula: $R_{GYRO} = \dfrac{RR_{AD}}{RK_G}$. among them $R_{AD} = 3.3V/4096$,

Show AD Conversion factor. $R_G = 0.67$ $mV \cdot$ deg / sec Gyro scale factor, the gyroscope data can manual

Found. $K = 5.1$ Gyro signal is magnification, the magnification can be calculated according to the preceding circuit parameters. will

Values into the above equation one can calculate the gyro scale factor: $R_{GYRO} = 0.24$ Since the existence of the above parameter

Errors, scale factor calculated above is only one reference value, we need to finalize the actual measured experimentally n

Determining the ratio value.

The method of experiment is the basic angle by changing an angle car models, comparison of the gyro obtained by integrating the amount of change

And the acceleration of gravity Z The amount of change is the same axis. Specific steps are as follows:

1) Algorithm first angle compensation circuit is opened;
Map 6-18 Measuring the scale factor of the gyro sensor, an angle compensation circuit is disconnected

2) Cars holding angle, measured Z And the output shaft angular acceleration integration angle output;

3) Cars changing the angle measurement Z Axis angle and the change in output angle variation acceleration integration;

in case Z Axis angle change amount of the gyro output angle variation are the same, then the current ratio gyroscope

Factor is correct. Otherwise, Z Angle change divided by two axis gyroscope angle variation, and then multiplied by the current ratio

Example factor can correct the gyro scale factor.

Since the existence of the integral gyro drift, so the above correction process needs fast. By repeatedly corrected, you can get

The exact scale factor of the gyroscope.

May not be the angle compensation circuit is disconnected, by the gyro output angle of the curve can also determine the ratio of the gyroscope

Factor is appropriate. If the small gyro scale factor, the gyro angle output will have a slow tracking process.

Conversely, if a large proportion of the factors gyroscope, the gyroscope will have an angle output overshoot. With a few adjustments, can

To give the correct scale factor of the gyroscope, the gyroscope so that the output angle of the gravitational acceleration can be tracked correctly Z Input shaft

Signal. Map 6-19 Shows the case where the gyro output angle of several different scale factor of the gyroscope.
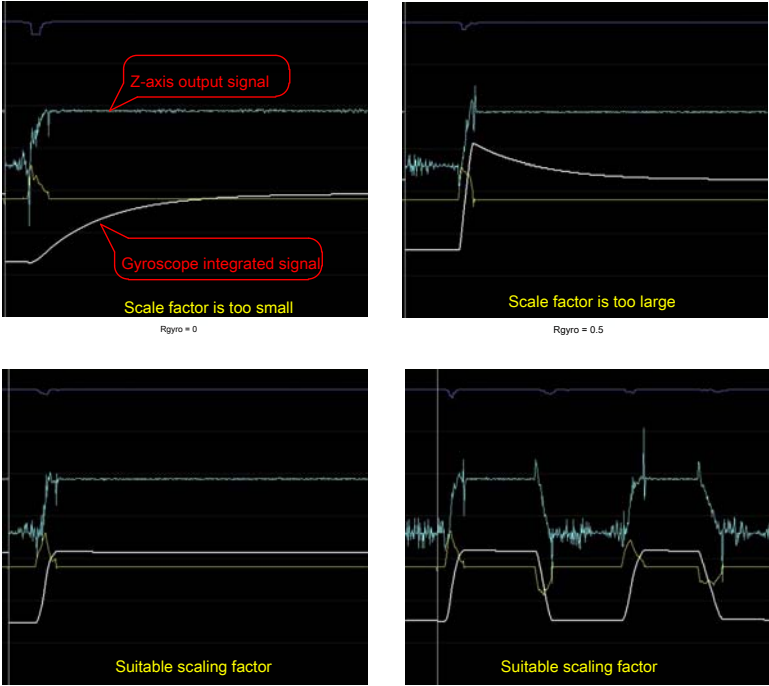

Map 6-19 Several different scale factor of the gyro angle output

If a map 2-32 Without gravitational acceleration control scheme shown, the sensor can be greatly simplified parameters

Tuning. Without gravity accelerometer sensor for measuring inclination of car models and car models gyroscope angle gyroscopes

Scale factor can not be corrected, the final performance of the different sensors to compensate by controlling parameters.

6.3.2. Cars static debugging control parameters

These follow the order of parameter adjustment, the order of the angle, speed, direction of adjustment. In these three groups of parameters adjustment

Process, and the time constant of the motor angle correction dead zone parameters are first set to a default value. For example, the angle

Compensation time constant T_Z can choose 3 second. Motor options for the dead V_D 0 . After completion of the preceding three tuning parameters into a

Further optimize these two parameters. It needs special emphasis has two aspects: The first aspect is the angle compensation T_Z constant be too

Small, analysis of the causes behind while adjusting the parameters. The second aspect is the zero point offset for each sensor as possible

Amendment accurate energy. If during debugging below zero offset any sensor drift occurred, the need for timely

Correction.

1 , The angle parameter setting

Angle proportional and derivative control parameters include two parameters. Scaling parameter P_{ANGLE} () is equivalent to an inverted pendulum reply

force. This parameter must be greater than the gravitational acceleration effect can be produced such that it remains upright car models. With this reference

Gradually increase the number, scale models began to be able to stay upright. This parameter is further increased, scale models began to swing back and forth now

Like. Differential parameter D_{ANGLE} corresponds to an inverted pendulum damping force, it can effectively suppress the swing car models. when

When this parameter is too large, it will cause shock car models themselves. This is because the car model itself is not a rigid body, the body has a

Given resonance frequency. Cars will be such that the time derivative parameter is too large resonance in the vehicle body driven by the motor.

Adjusting these two parameters can follow the process after the first derivative of proportion. First, adjust the scale parameter, such car models can be

Upright and start swinging back and forth. A statement to this scale parameter image has been overcome gravity. Then gradually

Increasing the differential parameters, scale models and gradually upright and stable. Cars began to increase the differential parameters until resonance, so that you

Determine the maximum value of the differential parameter. Differential parameter is then appropriately reduced, and then gradually increasing the proportion of para

He began to shock, so that we can determine the maximum proportion parameter. Then the appropriate reduction rate parameters. In these parameters

Tested several nearby until find a set of optimal control parameters Cars upright.

The specific process can see the following FIG. 6-21 As shown in the graphic.

Map 6-21 Angle parameter adjustment process

Cars upright proportional and derivative control parameters of a considerable range. Cars were moving behind the

Parameter adjustment leaves room for amendment.

Since the gravitational acceleration sensor and the gyro drift error signal that has the mounting, the angle control parameter adjusted

The car models are not sophisticated stay at a certain point. It is inclined towards the angular direction acceleration traveling car models. During this process,

Adjusted for multiple car models and zero gravitational parameter gyroscope, the inclination angle may be gradually eliminate car models,

But in the end with the sensor drift, scale models or will accelerate the move. Cars remain stationary or constant speed operation needs to pass

Overspeed control to achieve.

2 Speed parameter setting

After the initial parameters determining the angle, the speed can be controlled tuning parameters. Speed ratio control parameter includes

Example P_{SPEED}) and differential (D_{SPEED}) two control parameters, where the proportional and derivative feedback means is defined speed

Statements. If the position feedback Cars (integral amount of speed) with respect to these two parameters can also be referred to as a product corresponding to each

Min () and the ratio () parameter.
$_{SPEED}$ P_{SPEED}

Is achieved by adjusting the angle of the first car models Note that the speed modulation in nature. Map 2-38 Shows the

Speed control link. Speed error proportional control parameter determines the ability to inhibit, but only proportional control, the speed of car models

There will be a double integral control negative feedback control. The first integral is the integral of the error, the second is the integration of the inclination Cars

Acceleration generated points. Therefore, the speed of the car models will be a shock phenomenon. The shock can be eliminated by differential control

phenomenon.

When the adjustment, since the adjustment is static, therefore first speed setpoint speed control loop is set 0 . However

After started to adjust the proportional and derivative parameters behind. The first specific debugging process can gradually scaling parameters, scale models can

Be in the vicinity of Ping Heng point constant back and forth motion. Then gradually increase the differential parameter, scale models will soon remain in balance

Out. Use external shocks car models, car models can quickly become stationary. And then gradually increase the proportional and derivative control parameters,

Cars making resistance to external interference shocks gradually increase. Figure debugging process 6-22 Fig.

Map 6-22 Speed parameter adjustment process

When the proportional and derivative parameters up to a certain value, scale models began to swing phenomenon. At this point we can know the ratio

Differential and general scope. Through several tests the optimum adjustment can be preliminarily determined within this range of speed control parameters

combination.

3 , The direction parameter setting

A direction control includes two parameters: the proportional control parameter P_{DIR} () and the differential control parameter D_{DIR} (). Adjustment

Direction parameter is to set the speed parameter 0 , Open the Desktop 20kHz Electromagnetic power supply. Proportional control parameter may cause

Cars restore the correct direction of the position. When this parameter is gradually increasing, scale models direction response rate gradually accelerated. When the

After several increases to a certain value, due to the rapid response car models direction, the direction will overshoot. This phenomenon can be

Through FIG. 5-23 display. At this time, the control parameters can be suppressed by increasing the differential of direction overshoot phenomenon. by

Combination of several tests can select an appropriate set of proportional control and differential control parameters that control the direction of car models quickly i.e

It will not overshoot.

■ $P_{DIR}=0.1$ 控制比率值太小，几乎没有方向控制能力。

■ $P_{DIR}=0.25$ 有比较弱的方向控制能力。由于摩擦力的存在，车模不能够恢复到前向位置。

■ $P_{DIR}=0.5$ 方向控制能力强。回复到前向位置迅速，没有过冲。

■ $P_{DIR}=0.75$ 方向回复能力强，但是有过冲现象。

■ $P_{DIR}=1.0$ 方向恢复能力过于强，有强的过冲现象。

$P_{DIR}=0.1$ $P_{DIR}=0.25$ $P_{DIR}=0.5$ $P_{DIR}=0.75$ $P_{DIR}=1.0$

0

P_{DIR}参数

最终选择$P_{DIR}=0.5$

通过实验最终选择$P_{DIR}=0.5$。
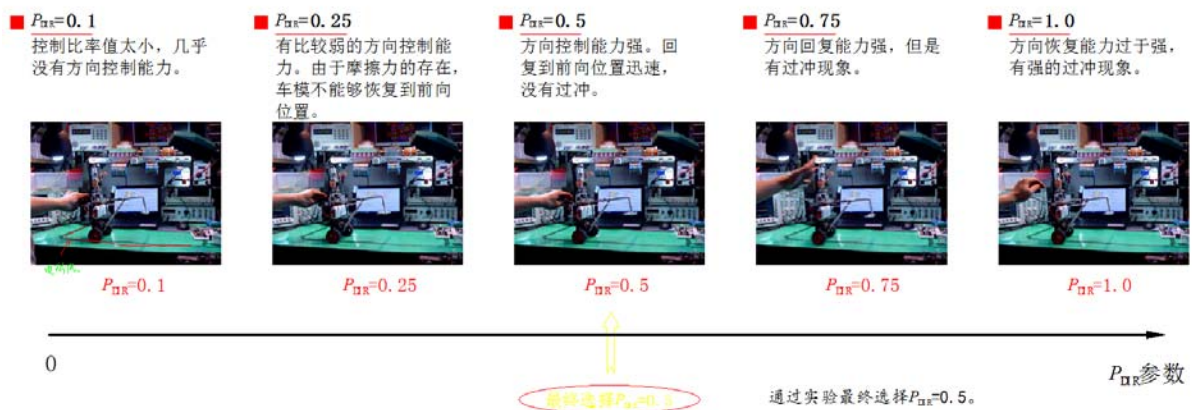

Map 6-23　Direction parameter adjustment process

If the directional control parameter adjustment is too large, it will affect the control car models angle. Therefore, in this process of debugging,

Cars need to balance the upright direction and both control stability.

The above three steps to adjust the angle of the car models, the speed and direction control. These parameters are stationary when the car models

Debugging. Have a mutual influence between them. Cars movement behind the front adjusted as compliance

Follow the principles and experience between them affect each other, and gradually optimizing these parameters such that during movement remains Cars

Stable and fast characteristics.

4 , Compensation time constant setting

Cars angle compensation time constant (T_z), determines the capacity of integrating gyro drift suppression, also determines the car

Speed control angle tracking mode speed, while the ability to determine the gravitational acceleration in the suppression of disturbing signals. Although it

Only one parameter, but it will also affect the adjustment of the angle and speed control. Wherein for controlling the angle of impact

Particularly evident.

Start adjusting the control parameters when the first three may be selected backoff time 3 to 4 Or so seconds. If Tuo

Spiro instrument zero drift is small, the compensation can be increased time constant. If the gyroscope zero drift large, you can

This gradually decreases the compensation time constant. Reduce the time constant when the compensation will find car models will now waggle

Like. When this phenomenon and control the angle of car models, the oscillatory phenomenon of car models consistent scale value generated is too large. So you ca

To increase the appropriate control parameters angle differential parameter D_{ANGLE} () to suppress the phenomenon of swing car models. See the debugging process

Map 6-24 Fig.

Map 6-24 Angle compensation time constant adjusting

Why angle compensation time constant is too small will cause car models swing it? FIG. 5-25 Carried on by the acceleration

Forces can be known gravitational acceleration sensor is mounted having a certain height, angle changes at this time car models, it

Will gravitational acceleration sensor Z Axis acceleration component appears. This inclination is proportional to the acceleration component of car models. Such as

If at this time the compensation angle gravitational acceleration constant is too small, corresponding to the angle calculation loop analysis can know, at this time Z ax

Since the signal of the acceleration caused by the angle of the car models exactly offset the differential angle control component in the original, so that the vehicle

Mold will swing back and forth, therefore the need to increase the angle of the derivative component of the control to suppress the swing car models. Map 5-25

Cars swing elimination can be achieved by two methods, one is to increase the time constant of the compensation T_2, this solution also

To release the preceding claims when the compensation time constant adjustment parameter Why reason not be too small. The second way is through

Reducing the height of the angular velocity sensor to reduce the swing car models

5 The motor constant setting deadband

Cars in the drivetrain, all aspects of the existence of static friction, it will reduce car models static stability.

It can be overcome by increasing the voltage to the motor control a constant dead space.

When adjusting dead zone constant need to remain upright stationary car models. Deadband constant 0 When, scale models will be at rest

Back and forth back and forth movement of small amplitude appear. By gradually increasing the dead zone constant back and forth motion car models phenomenon

Dead time constant is too large, there will be car models motor vibration phenomenon. Figure 5-26 Fig.

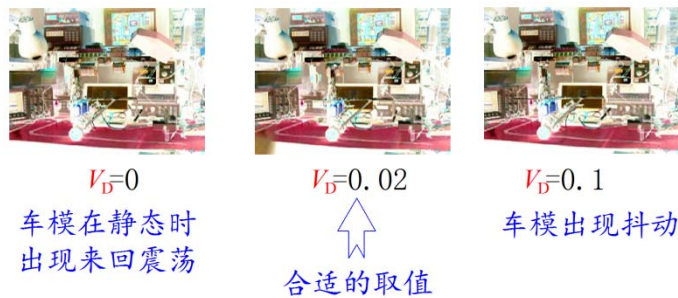

Map 6-26 Deadband constant adjustment

By gradual adjustment may determine a relatively modest deadband constant.

In the smart car competition it is, because it is the speed of the game. Deadband constant of the motor may be provided to 0 ,it

For car models did not affect the high-speed operation.

6.4 Site debugging dynamic parameters

By the above steps, determining the parameters of each phase of the control link. However, these parameters are the speed of the car models

Remains 0 For debugging in the state. Are these parameters are in with a good run at high speed car models, but also

"It is the mule is a horse, pull out yo." Therefore, the high-speed car models running on the race track again for each

Control parameters are optimized, so that the car models run fast and stable.

Dynamic adjustment of the various parameters is generally based on the obtained static adjustment, gradually increase the speed set Cars

Value observed at different car models operating speed setpoint, its angle, speed and direction control performance. In Bulgaria

Cars under license angle and direction of stable conditions, and gradually increase the speed of the car models, observed phenomena appear, according to the

Adjust control parameters preceding the interaction therebetween relationship obtained by adjusting parameters, such car models and can be

Gu stability and speed.

Cars running on, adjust the control parameters are very complex. This process needs to be tested repeatedly. Tested

Process, went off the track in order to avoid runaway Cars damaged hits an obstacle, it is recommended to increase in the wireless remote control car models

Switch, can be stopped in an emergency car models.

Cars test track complex needs as much as possible under the conditions allow for racetrack elements that may arise

Hope can be tested to find the optimal parameters of car models in a variety of extreme track conditions, as well as the fastest possible speed

Degree setting, which is behind the development of competition policy to participate in a live game basis. When the game scene, often available on-site

Debugging time does not allow players to race track complete test, therefore there is need to select the characteristics of the track section into

Line testing, and finally given a reasonable control parameters. Select what part of the track for testing, usually you need to dynamically adjust

The test of experience.

Cars dynamic debugging is not only adjusted for various control parameters, while the mechanical structure of the car models also measured

Test and adjust. Within a predetermined range of the rules of the game, and arrange the center of gravity position of the sensor mounting position of car models,

Improve the stability of the car models. In the fourth chapter describes the installation error will cause the gyroscope car models increase the speed when cornering c

cut back. Thus, it is possible to adjust the mounting angle of the gyro car models by dynamic operation. After an additional electromagnetic Cars

When crossing an intersection, by controlling the direction of car models electromagnetic sensor determines whether the installation is stable level.

6.5 Program improvement and improve the overall level of car models

Car models after production, programming, after commissioning, operation carried out in the real world, the existence of further errors are found,

Optimization of the various control parameters, and gradually increase the running speed of the car models. Through continuous running, as amended, was an optim

Control Strategy.

In the test run, or we can make further improvements to the control algorithm. Cars increase state observations, which correction

Nonlinear links, improve stability and performance, the car models in the high-speed operation.

No Limit game, the endless pursuit. Debugging on the results already achieved, careful observation, careful thought, to

To the problems identified, the gradual improvement of the control scheme, breaking the limitations of existing ideas, seek more advanced perfect solution,

In order to win the next competition. Within the specified range of game technology, the pursuit of excellence. In the continuous improvement and real

Experiment, the harvest is not only the final race results, but also the ability and the courage to do it yourself spirit of exploration.

Chapter VII Conclusion

As used herein, the theoretical knowledge as few car models control scheme described with reference to upright walking. Through this square

Case, the students will feel to walk upright produced car models contest is not a difficult thing, but quite easy and fun

the process of.

By making, students can basically achieve complete race car models. Upon completion, students will gradually find

The shortcomings of the program, and thus improve the germination of the idea. To simplify the design of the control scheme, herein in many ways

It has been simplified. Cars need to realize such control is achieved by controlling the acceleration of the motor, at the start of presentation

Designate, for motor acceleration control is to alter the drive voltage of the motor. But the acceleration of the motor should be through

Wherein the electromagnetic torque generated by the current to achieve. This requires motor control circuit should be increased on the current control

Cars have a system which can ensure more stable performance. According to their knowledge and experience made, students can

Circuit design, control algorithms, mechanical adjustments can be found in many areas of improvement. In order to achieve these improvements

The idea, take out more of the relevant literature, learning advanced modern control theory knowledge and improve their theoretical level and

Practical ability, eventually produce automatic gain control for Qiang Lie professional interest, which is what the students deserve.

Cars made in the program of the competition, we should try to choose inexpensive, easy to buy the device. in order to avoid

Teams use expensive sensor device in terms of choice, the competition rules defined so that an acceleration sensor and a gyro

Model used. Taking into account changes in the future availability of sensor market, the organizing committee will expand the range of the sensor selected.

Please pay attention to the team members timely information published on the website of the competition.

Cars race this year to walk upright is first established, the students produced electromagnetic group walk upright running car models

Speed may be relatively slow, therefore limiting the length and difficulty of the race track in the competition rules. Meanwhile, in the game

Process, does not require a static car models from two seconds to automatically start the race, was canceled at the end of the game Cars stopped at the starting

Required track on-line within three meters. Competition Organizing Committee will be based on the specific circumstances of the students made car models, the elec

Race track, rules of the game for further revision, the revised information will be promptly posted on the competition website.
